#### Abstract

A word is called a reset word for a deterministic finite automaton if it maps all the states of the automaton to a unique state. Deciding about the existence of a reset word of a given length for a given automaton is known to be an NP-complete problem. We prove that it remains NP-complete even if restricted to Eulerian automata with binary alphabets as it has been conjectured by Martyugin (2011).

## 1. Introduction and preliminaries

A deterministic finite automaton is a triple $A=(Q, X, \delta)$, where $Q$ and $X$ are finite sets and $\delta$ is an arbitrary mapping $Q \times X \rightarrow Q$. Elements of $Q$ are called states, $X$ is the alphabet. The transition function $\delta$ can be naturally extended to $Q \times X^{\star} \rightarrow Q$, still denoted by $\delta$. We extend it also by defining

$$
\delta(S, w)=\left\{\delta(s, w) \mid s \in S, w \in X^{\star}\right\}
$$

for each $S \subseteq Q$. If the automaton is fixed, we write

$$
r \xrightarrow{w} s
$$

instead of $\delta(r, w)=s$.
For a given automaton $A=(Q, X, \delta)$, we call $w \in X^{\star}$ a reset word if

$$
|\delta(Q, w)|=1
$$

If such a word exists, we call the automaton synchronizing. Note that each word having a reset word as a factor is also a reset word.

A need for finding reset words appears in several fields of mathematics and engineering. Classical applications (see [14]) include model-based testing, robotic manipulation, and symbolic dynamics, but there are important connections also with information theory [13] and with formal models of biomolecular processes [2].

The Černý Conjecture, a longstanding open problem, claims that each synchronizing automaton has a reset word of length at most $(|Q|-1)^{2}$. Though it still remains open, there are many weaker results in this field, see e.g. [11,7] for recent ones. ${ }^{1}$

[^0]http://dx.doi.org/10.1016/j.ic.2016.06.013

Various computational problems arise from the study of synchronization:

- Given an automaton, decide whether it is synchronizing. Relatively simple algorithm, which could be traced back to [3], works in polynomial time.
- Given a synchronizing automaton and a number d, decide whether $d$ is the length of shortest reset words. This has been shown to be both NP-hard [4] and coNP-hard. More precisely, it is DP-complete [10]. See also [1] and [5] for recent nonapproximability results concerning an optimization setting.
- Given a synchronizing automaton and a number d, decide whether there exists a reset word of length $d$. This problem is of our interest. Lying in NP, it is not so computationally hard as the previous problem. However, it is proven to be NPcomplete [4]. Following the notation of [9], we call it Syn. Assuming that $\mathcal{M}$ is a class of automata and membership in $\mathcal{M}$ is polynomially decidable, we define a restricted problem:

```
Syn(\mathcal{M})
Input: synchronizing automaton }A\in\mathcal{M},d\in\mathbb{N
Output: does }A\mathrm{ have a reset word of length }d\mathrm{ ?
```

An automaton $A=(Q, X, \delta)$ is Eulerian if

$$
\sum_{x \in X}|\{r \in Q \mid \delta(r, x)=q\}|=|X|
$$

for each $q \in Q$. Informally, there should be exactly $|X|$ transitions incoming to each state. An automaton is binary if $|X|=2$. The classes of Eulerian and binary automata are denoted by $\mathcal{E U}$ and $\mathcal{A} \mathcal{L}_{2}$ respectively.

Previous results about various restrictions of Syn can be found in $[4,8,9]$. Some of these problems turned out to be polynomially solvable, others are NP-complete. In [9] Martyugin conjectured that $\operatorname{SyN}\left(\mathcal{E U} \cap \mathcal{A} \mathcal{L}_{2}\right)$ is NP-complete. This conjecture is confirmed in the rest of the present paper.

## 2. Main result

### 2.1. Proof outline

We prove the NP-completeness of $\operatorname{SyN}\left(\mathcal{E Z} \cap \mathcal{A} \mathcal{L}_{2}\right)$ by a polynomial reduction from 3-SAT. So, for an arbitrary propositional formula $\phi$ in 3-CNF we construct an Eulerian binary automaton $A$ and a number $d$ such that

$$
\begin{equation*}
\phi \text { is satisfiable } \Leftrightarrow A \text { has a reset word of length } d \text {. } \tag{1}
\end{equation*}
$$

For the rest of the paper we fix a formula

$$
\phi=\bigwedge_{i=1}^{m} \bigvee_{\lambda \in C_{i}} \lambda
$$

on $n$ variables, where each $C_{i}$ is a three-element set of literals, i.e., a subset of

$$
L_{\phi}=\left\{x_{1}, \ldots, x_{n}, \neg x_{1}, \ldots, \neg x_{n}\right\} .
$$

We index the literals $\lambda \in L_{\phi}$ by the following mapping $\kappa$ :

| $\lambda$ | $x_{1}$ | $x_{2}$ | $\ldots$ | $x_{n}$ | $\neg x_{1}$ | $\neg x_{2}$ | $\ldots$ | $\neg x_{n}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\kappa(\lambda)$ | 0 | 1 | $\ldots$ | $n-1$ | $n$ | $n+1$ | $\ldots$ | $2 n-1$ |

Let $A=(Q, X, \delta), X=\{a, b\}$. Because the structure of the automaton $A$ will be very heterogeneous, we use an unusul method of description. The basic principles of the method are:

- We describe the automaton $A$ via a labeled directed multigraph $G$, representing the automaton in a standard way: edges of $G$ are labeled by single letters $a$ and $b$ and carry the structure of the function $\delta$. Paths in $G$ are thus labeled by words from $\{a, b\}^{\star}$.
- There is a collection of labeled directed multigraphs called templates. The graph $G$ is one of them. Another template is SINGLE, which consists of one vertex and no edges.
- Each template $T \neq S I N G L E$ is expressed in a fixed way as a disjoint union through the set PARTS $_{T}$ of its proper subgraphs (the parts of $T$ ), extended by a set of additional edges (the links of $T$ ). Each $H \in$ PARTS $_{T}$ is isomorphic to some template U . We say that $H$ is of type U .

Fig. 1. Template ABS.

Fig. 2. A barrier of ABS parts.

Fig. 3. Templates CCA, CCI and $\operatorname{PIPE}(d)$ respectively.

- Let $q$ be a vertex of a template T , lying in a subgraph $H \in \mathrm{PARTS}_{\mathrm{T}}$ which is of type U via a vertex mapping $\rho: H \rightarrow \mathrm{U}$. The local address $\operatorname{adr}_{\mathrm{T}}(q)$ is a finite string of identifiers separated by „|". It is defined inductively by

$$
\operatorname{adr}_{\mathrm{T}}(q)= \begin{cases}H \mid \operatorname{adr}_{\mathrm{U}}(\rho(q)) & \text { if } \mathrm{U} \neq \text { SINGLE, } \\ H & \text { if } \mathrm{U}=\text { SINGLE. }\end{cases}
$$

The string $\operatorname{adr}_{G}(q)$ is used as a regular vertex identifier.
Having a word $w \in X^{\star}$, we denote a $t$-th letter of $w$ by $w_{t}$ and define the set $S_{t}=\delta\left(Q, w_{1} \ldots w_{t}\right)$ of active states at time $t$. Whenever we depict a graph, a solid arrow stands for the label $a$ and a dotted arrow stands for the label $b$.

### 2.2. Description of the graph $G$

Let us define all the templates and informally comment on their purpose. Fig. 1 defines the template ABS, which does not depend on the formula $\phi$.

The state out of a part of type ABS is always inactive after application of a word of length at least 2 which does not contain $b^{2}$ as a factor. This allows us to ensure the existence of a relatively short reset word. Actually, large areas of the graph (namely the CLAUSE (... ) parts) have roughly the shape depicted in Fig. 2, a cylindrical structure with a horizontal barrier of ABS parts. If we use a sufficiently long word with no occurrence of $b^{2}$, the edges outgoing from the ABS parts are never used and almost all states become inactive.

Fig. 3 defines simple templates CCA, CCI and $\operatorname{PIPE}(d)$ for a given length $d \geq 1$. The activity of an out state depends on the last two letters applied. In the case of CCA it is inactive if (and typically only if) the two letters were equal. In the case of CCI it works oppositely, equal letters correspond to active out state. One of the key ideas of the entire construction is the following. Let there be a subgraph of the form

$$
\begin{gathered}
\text { part of type PIPE }(d) \\
\downarrow a, b \\
\text { part of type CCA or CCI } \\
\downarrow a, b
\end{gathered}
$$

part of type PIPE (d).
Before the synchronization process starts, all the states are active. As soon as the second letter of an input word is applied, the activity of the out state starts to depend on the last two letters and the pipe below keeps a record of its previous activity. We say that a part $H$ of type PIPE (d) records a sequence $B_{1} \ldots B_{d} \in\{\mathbf{0}, \mathbf{1}\}^{d}$ at time $t$, if it holds that

$$
B_{k}=\mathbf{1} \Leftrightarrow H \mid s_{k} \notin S_{t} .
$$

Fig. 4. Templates $\operatorname{INC}(\lambda)$ and NOTINC $(\lambda)$.

Fig. 5. Template TESTER.

In order to continue with defining templates, let us define a set $M_{\phi}$ containing all the literals from $L_{\phi}$ and some auxiliary symbols:

$$
M_{\phi}=L_{\phi} \cup\left\{y_{1}, \ldots, y_{n}\right\} \cup\left\{z_{1}, \ldots, z_{n}\right\} \cup\left\{q, q^{\prime}, r, r^{\prime}\right\} .
$$

We index the $4 n+4$ members $\nu \in M_{\phi}$ by the following mapping $\mu$ :

| $\nu$ | $q$ | $r$ | $y_{1}$ | $x_{1}$ | $y_{2}$ | $x_{2}$ | $\ldots$ | $y_{n}$ | $x_{n}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mu(\nu)$ | 1 | 2 | 3 | 4 | 5 | 6 |  | $2 n+1$ | $2 n+2$ |
|  |  |  |  |  |  |  |  |  |  |
| $\nu$ | $q^{\prime}$ | $r^{\prime}$ | $z_{1}$ | $\neg x_{1}$ | $z_{2}$ | $\neg x_{2}$ | $\ldots$ | $z_{n}$ | $\neg x_{n}$ |
| $\mu(\nu)$ | $2 n+3$ | $2 n+4$ | $2 n+5$ | $2 n+6$ | $2 n+7$ | $2 n+8$ | $\ldots$ | $4 n+3$ | $4 n+4$ |

The inverse mapping is denoted by $\mu^{-1}$. For each $\lambda \in L_{\phi}$ we define templates INC $(\lambda)$ and $\operatorname{NOTINC}(\lambda)$, both consisting of $12 n+12$ SINGLE parts identified by the elements of $\{1,2,3\} \times M_{\phi}$. As depicted in Fig. 4a, the links of INC $(\lambda)$ are:
$(1, v) \xrightarrow{a} \begin{cases}(2, \lambda) & \text { if } v=\lambda \text { or } v=r, \\ (2, v) & \text { otherwise },\end{cases}$
$(1, v) \xrightarrow{b} \begin{cases}(2, r) & \text { if } v=\lambda \text { or } v=r, \\ (2, v) & \text { otherwise },\end{cases}$
$(2, v) \xrightarrow{a} \begin{cases}(3, q) & \text { if } v=r \text { or } v=q, \\ (3, v) & \text { otherwise },\end{cases}$
$(2, v) \xrightarrow{b} \begin{cases}(3, r) & \text { if } v=r \text { or } v=q, \\ (3, v) & \text { otherwise. }\end{cases}$

Note that we use the same identifier for a one-vertex subgraph and for its vertex. As it is clear from Fig. 4b, the links of NOTINC ( $\lambda$ ) are:

Fig. 6. Templates FORCER and LIMITER respectively.

The key property of such templates comes to light when we need to apply some two-letter word in order to make the state $(3, \lambda)$ inactive assuming ( $1, r$ ) inactive. If also $(1, \lambda)$ is initially inactive, we can use the word $a^{2}$ in both templates. If it is active (which corresponds to the idea of unsatisfied literal $\lambda$ ), we discover the difference between the two templates: The word $a^{2}$ works if the type is $\operatorname{NOTINC}(\lambda)$, but fails in the case of $\operatorname{INC}(\lambda)$. Such failure corresponds to the idea of unsatisfied literal $\lambda$ occurring in a clause of $\phi$.

For each $i$-th clause we define the template $\operatorname{TESTER}(i)$. It consists of $2 n$ serially linked parts, namely level $l_{\lambda}$ for each $\lambda \in L_{\phi}$, each of type $\operatorname{INC}(\lambda)$ or $\operatorname{NOTINC}(\lambda)$. The particular type of each level depends on the clause $C_{i}$ as seen in Fig. 5, so exactly three of them are always of type INC (...). If the corresponding clause is unsatisfied, each of its three literals is unsatisfied, which causes three failures within the levels. Three failures imply at least three occurrences of $b$, which turns up to be too much for a reset word of certain length to exist. Clearly we still need some additional mechanisms to implement this vague vision.

Fig. 6 defines templates FORCER and LIMITER. The idea of template FORCER is simple. Imagine a situation when $q_{1,0}$ or $r_{1,0}$ is active and we need to deactivate the entire forcer by a word of length at most $2 n+3$. Any use of $b$ would cause an unbearable delay, so if such a word exists, it starts by $a^{2 n+2}$.

The idea of LIMITER is similar, but we tolerate some occurrences of $b$ here, namely two of them. This works if we assume $s_{1,0}$ active and it is necessary to deactivate the entire limiter by a word of length at most $6 n+1$.

We also need a template $\operatorname{PIPES}(d, k)$ for each $d, k \geq 1$. It consists just of $k$ parallel pipes of length $d$. Namely there is a SINGLE part $s_{d^{\prime}, k^{\prime}}$ for each $d^{\prime}<d, k^{\prime} \leq k$ and all the edges are of the form $s_{d^{\prime}, k^{\prime}} \longrightarrow s_{d^{\prime}+1, k^{\prime}}$.

The most complex templates are CLAUSE ( $i$ ) for each $i \in\{1, \ldots, m\}$. Denote

$$
\begin{aligned}
\alpha_{i} & =(i-1)(12 n-2), \\
\beta_{i} & =(m-i)(12 n-2) .
\end{aligned}
$$

As shown in Fig. 7, CLAUSE ( $i$ ) consists of the following parts:

- Parts $s p_{1}, \ldots, s p_{4 n+6}$ of type SINGLE. The acronym $s p$ stands for spine.
- Parts $a b s_{1}, \ldots, a b s_{4 n+6}$ of type ABS. The entire template has a shape similar to Fig. 2, including the barrier of ABS parts.
- Parts pipe ${ }_{\mathrm{B}}$, pipe $_{\mathrm{F}}$, pipe $_{\mathrm{H}}$ of types $\operatorname{PIPE}(2 n-1)$ and pipe ${ }_{\mathrm{G}}$, pipe $_{\mathrm{I}}$ of types $\operatorname{PIPE}(2 n+2)$.
- Parts cca and cci of types CCA and CCI respectively. Together with the pipes above they realize the idea described in (2). As they form two constellations which work simultaneously, the parts pipe ${ }_{\mathrm{G}}$ and pipe typically record mutually inverse sequences. We interpret them as an assignment of the variables $x_{1}, \ldots, x_{n}$. Such assignment is then processed by the tester.
- A part $v$ of type SINGLE for each $\nu \in M_{\phi}$.
- A part tester of type TESTER (i).
- A part $\bar{\lambda}$ of type SINGLE for each $\lambda \in L_{\phi}$. While describing the templates INC $(\lambda)$ and $\operatorname{NOTINC}(\lambda)$ we claimed that in certain case there arises a need to make the state $(3, \lambda)$ inactive. This happens when the border of inactive area

Fig. 7. Template CLAUSE ( $i$ ).
moves down through the tester levels. The point is that any word of length $6 n$ deactivates the entire tester, but we need to ensure that some tester columns, namely the $\kappa(\lambda)$-th for each $\lambda \in L_{\phi}$, are deactivated one step earlier. If some of them is still active just before the deactivation of tester finishes, the state $\bar{\lambda}$ becomes active, which slows down the synchronization process.

- Parts pipes $_{\mathrm{J}}$, pipes $_{\mathrm{K}}$ and pipes $_{\mathrm{L}}$ of types PIPES $\left(\alpha_{i}, 4 n+4\right)$, $\operatorname{PIPES}(6 n-2,4 n+4)$ and $\operatorname{PIPES}\left(\beta_{i}, 4 n+4\right)$ respectively. There are multiple clauses in $\phi$, but multiple testers cannot work in parallel. That is why each of them is padded by a passive PIPES (...) part of size depending on particular $i$. If $\alpha_{i}=0$ or $\beta_{i}=0$, the corresponding PIPES part is not present in CLAUSE ( $i$ ).
- Parts pipe ${ }_{\mathrm{A}}$, pipe $_{\mathrm{C}}$, pipe $_{\mathrm{D}}$, pipe $_{\mathrm{E}}$ of types $\operatorname{PIPE}(12 m n+4 n-2 m+6), \operatorname{PIPE}(4), \operatorname{PIPE}\left(\alpha_{i}+6 n-1\right)$, $\operatorname{PIPE}\left(\beta_{i}\right)$ respectively.
- A part forcer of type FORCER. This part guarantees that only the letter $a$ is used in certain segment of the word $w$. This is necessary for the data produced by cca and cci to safely leave the parts pipe ${ }_{\mathrm{F}}$, pipe $\mathrm{H}_{\mathrm{H}}$ and line up in the states of the form $v$ for $v \in M_{\phi}$, from where they are shifted to the tester.
- A part limiter of type LIMITER. This part guarantees that the letter $b$ occurs at most twice when the border of inactive area passes through the tester. Because each unsatisfied literal from the clause requests an occurrence of $b$, only a satisfied clause meets all the conditions for a reset word of certain length to exist.

See also Table 1. Links of CLAUSE( $i$ ) that may not be clear from Fig. 7 are

Table 1
Length of selected parts of CLAUSE (i)

| Part | Length |
| :--- | :--- |
| pipe $_{\mathrm{A}}$ | $12 m n+4 n-2 m+6$ |
| pipe $_{\mathrm{B}}$ | $2 n-1$ |
| pipe $_{\mathrm{C}}$ | 4 |
| pipe $_{\mathrm{D}}$ | $\alpha_{i}+6 n-1$ |
| pipe $_{\mathrm{E}}$ | $\beta_{i}$ |
| pipe $_{\mathrm{F}}$ | $2 n-1$ |

| Part | Length |
| :--- | :--- |
| pipe $_{\mathrm{G}}$ | $2 n+2$ |
| pipe $_{\mathrm{H}}$ | $2 n-1$ |
| pipe $_{\mathrm{I}}$ | $2 n+2$ |
| pipes $_{\mathrm{J}}$ | $\alpha_{i}$ |
| pipes $_{\mathrm{K}}$ | $6 n-2$ |
| pipes $_{\mathrm{L}}$ | $\beta_{\mathrm{i}}$ |

Fig. 8. The graph $G$.

$$
v \xrightarrow{a}\left\{\left.\begin{array}{ll}
\operatorname{pipes}_{\mathrm{J}} \mid s_{1, \mu(v)} & \text { if } v \in\left\{x_{n}, \neg x_{n}\right\}, \\
\mu^{-1}(\mu(v)+1) & \text { otherwise, }
\end{array} \quad v \xrightarrow{b} \operatorname{pipes}_{\mathrm{J}} \right\rvert\, s_{1, \mu(v)}\right.
$$

for each $v \in M_{\phi}$ and

$$
\text { pipes }_{\mathrm{L}} \left\lvert\, s_{\beta_{i}, k} \xrightarrow{a, b}\left\{\left.\begin{array}{ll}
\overline{\mu^{-1}(k)} & \text { if } \mu^{-1}(k) \in L_{\phi}, \\
a b s_{k+2} \mid \text { in } & \text { otherwise },
\end{array} \quad \bar{\lambda} \xrightarrow{a, b} a b s_{\mu(\lambda)+2} \right\rvert\,\right. \text { in }\right.
$$

for each $k \in\{1, \ldots, 4 n+4\}, \lambda \in L_{\phi}$. Note that we rely on the addressing system introduced in Section 2.1.
We are ready to form the whole graph $G$, see Fig. 8. For each $i \in\{1, \ldots m\}$ there are parts $c l_{i}, a b s_{i}$ of types CLAUSE ( $i$ ) and ABS, respectively, and parts $q_{i}, r_{i}, r_{i}^{\prime}$ of type SINGLE. The parts $s_{1}, s_{2}$ are of type SINGLE as well. The edge incoming to a $c l_{i}$ part ends in $c l_{i} \mid s p_{1}$, the outgoing $b$-edge one starts in $c l_{i} \mid s p_{4 n+6}$. When no states outside $A B S$ parts are active within each CLAUSE (...) part and no out, $r_{1}$ nor $r_{2}$ state is active in any ABS part, the word $b^{2} a b^{4 n+m+7}$ takes all active states to $s_{2}$ and completes the synchronization.

Graph $G$ does not fully represent the automaton $A$ yet because there are

- $8 m n+4 m$ vertices with only one outgoing edge, namely $c l_{i}\left|a b s_{k}\right| o u t$ and $c l_{i} \mid s p_{l}$ for each $i \in\{1, \ldots, m\}, k \in\{1, \ldots, 4 n+6\}$, $l \in\{7, \ldots, 4 n+4\}$,
- $8 m n+4 m$ vertices with only one incoming edge: $c l_{i} \mid \nu$ and $c l_{i} \mid$ pipes $_{\mathrm{J}} \mid\left(1, v^{\prime}\right)$ for each $i \in\{1, \ldots, m\}, v \in M_{\phi} \backslash\left\{q, q^{\prime}\right\}$, $\nu^{\prime} \in M_{\phi} \backslash\left\{x_{n}, \neg x_{n}\right\}$.

We do not need to specify the missing edges exactly, let us just say that they somehow connect the relevant states so that the automaton $A$ is complete and Eulerian. Let us set

$$
d=12 m n+8 n-m+18
$$

and prove that the equivalence (1) holds.

### 2.3. From an assignment to a word

First, let us suppose that there is an assignment $\xi_{1}, \ldots, \xi_{n} \in\{\mathbf{0}, \mathbf{1}\}$ of the variables $x_{1}, \ldots, x_{n}$ (respectively) satisfying the formula $\phi$ and prove that the automaton $A$ has a reset word $w$ of length $d$. For each $j \in\{1, \ldots, n\}$ we denote

$$
\sigma_{j}= \begin{cases}a & \text { if } \xi_{j}=\mathbf{1} \\ b & \text { if } \xi_{j}=\mathbf{0}\end{cases}
$$

and for each $i \in\{1, \ldots, m\}$ we choose a satisfied literal $\bar{\lambda}_{i}$ from $C_{i}$. We set

$$
w=a^{2}\left(\sigma_{n} a\right)\left(\sigma_{n-1} a\right) \ldots\left(\sigma_{1} a\right) a b a^{2 n+3} b\left(a^{6 n-2} v_{1}\right) \ldots\left(a^{6 n-2} v_{m}\right) b^{2} a b^{4 n+m+7},
$$

where for each $i \in\{1, \ldots, m\}$ we use the word

$$
v_{i}=u_{i, x_{1}} \ldots u_{i, x_{n}} u_{i,-x_{1}} \ldots u_{i,-x_{n}},
$$

denoting

$$
u_{i, \lambda}= \begin{cases}a^{3} & \text { if } \lambda=\bar{\lambda}_{i} \text { or } \lambda \notin C_{i}, \\ b a^{2} & \text { if } \lambda \neq \bar{\lambda}_{i} \text { and } \lambda \in C_{i}\end{cases}
$$

for each $\lambda \in L_{\phi}$. We see that $\left|v_{i}\right|=6 n$ and therefore

$$
|w|=4 n+8+m(12 n-2)+4 n+m+10=12 m n+8 n-m+18=d .
$$

Let us denote

$$
\gamma=12 m n+4 n-2 m+9
$$

and

$$
\bar{S}_{t}=Q \backslash S_{t}
$$

for each $t \leq d$. Because the first occurrence of $b^{2}$ in $w$ starts at the $\gamma$-th position, we have:
Lemma 2.1. Each state of the form cl...|abs...|out or abs...| out lies in $\bar{S}_{2} \cap \cdots \cap \bar{S}_{\gamma}$.
Let us fix an arbitrary $i \in\{1, \ldots, m\}$ and describe a growing area of inactive states within $c l_{i}$. We use the following method of verifying inactivity of states: Having a state $s \in Q$ and $t, k \geq 1$ such that any path of length $k$ ending in $s$ contains a member of $\bar{S}_{t-k} \cap \cdots \cap \bar{S}_{t-1}$, we easily deduce that $s \in \bar{S}_{t}$. In such case let us just say that $k$ witnesses that $s \in \bar{S}_{t}$. The following claims follow directly from the definition of $w$. Note that Claim 7 relies on the fact that $b$ occurs only twice in $v_{i}$ :

## Lemma 2.2.

1. $\left\{c l_{i}\left|s p_{1}, \ldots, c l_{i}\right| s p_{4 n+6}\right\} \subseteq \bar{S}_{2} \cap \cdots \cap \bar{S}_{\gamma}$
2. $c l_{i}\left|p i p_{\mathrm{B}} \cup c l_{i}\right| p i p e_{\mathrm{F}} \cup c l_{i} \mid p i p e_{\mathrm{H}} \subseteq \bar{s}_{2 n+1} \cap \cdots \cap \bar{s}_{\gamma}$
3. $c l_{i}\left|c c a \cup c l_{i}\right| c c i \cup c l_{i} \mid p$ ipe $_{C} \quad \subseteq \bar{s}_{2 n+5} \cap \cdots \cap \bar{s}_{\gamma}$
4. $\quad c l_{i} \mid$ pipe $_{G} \cup c l_{i} \mid$ pipe $\cup \mathcal{C l}_{i} \mid$ forcer $\subseteq \bar{s}_{4 n+7} \cap \cdots \cap \bar{s}_{\gamma}$
5. $\left\{c_{i} \mid \nu: v \in M_{\phi}\right\} \quad \subseteq \bar{S}_{4 n+8} \cap \cdots \cap \bar{S}_{\gamma}$
6. $\quad c l_{i} \mid$ pipes $_{\mathrm{J}} \cup c l_{i} \mid$ pipes $_{\mathrm{K}} \cup \operatorname{cl}_{i} \mid$ pipe $_{\mathrm{D}} \subseteq \bar{S}_{10 n+\alpha_{i}+6} \cap \cdots \cap \bar{S}_{\gamma}$
7. cli $_{i} \mid$ limiter $\cup c_{i} \mid$ tester $\subseteq \bar{S}_{16 n+\alpha_{i}+6} \cap \cdots \cap \bar{S}_{\gamma}$
8. $\quad c_{i}\left|p i p e_{\mathrm{A}} \cup c l_{i}\right|$ pipe $_{\mathrm{E}} \cup \mathcal{l l}_{i} \mid$ pipes $_{\mathrm{L}} \subseteq \bar{s}_{\gamma-1} \cap \bar{S}_{\gamma}$

Proof. 1. Claim: $\left\{c l_{i}\left|s p_{1}, \ldots, c l_{i}\right| s p_{4 n+6}\right\} \subseteq \bar{S}_{2} \cap \cdots \cap \bar{S}_{\gamma}$.
We have $w_{1} w_{2}=a^{2}$ and there is no path labeled by $a^{2}$ ending in any $c l_{i} \mid s p \ldots$... state, so such states lie in $\bar{S}_{2}$. For each $t=3, \ldots, \gamma$ we can inductively use $k=1$ to witness the memberships in $\bar{S}_{t}$. In the induction step we use Lemma 2.1, which excludes the out states of the ABS parts from each corresponding $\bar{S}_{t-1}$.

All the memberships are witnessed by $k=2 n-1$, because any path of the length $2 n-1$ ending in such state must use a $c l_{i} \mid s p \ldots$... state and such states lie in $\bar{S}_{2} \cap \cdots \cap \bar{S}_{\gamma}$ by the previous claim.
3. Claim: $c_{i}\left|c c a \cup c l_{i}\right| c c i \cup c l_{i} \mid p i p e_{c} \subseteq \bar{S}_{2 n+5} \cap \cdots \cap \bar{S}_{\gamma}$.

We have $w_{2 n+2} \ldots w_{2 n+5}=a^{2} b a$, which clearly maps each state of $c l_{i}\left|c c a, c l_{i}\right| c c i$ or $c l_{i} \mid p i p e_{C}$ out of those parts. Each path of length 4 leading into the parts from outside starts in $\bar{S}_{2 n+1}$, so it follows that all the states lie in $\bar{S}_{2 n+5}$. To prove the rest we inductively use the witness $k=1$.
4. Claim: $c_{i} \mid$ pipe ${ }_{G} \cup c_{i} \mid$ pipe $e_{I} \cup c l_{i} \mid$ forcer $\subseteq \bar{S}_{4 n+7} \cap \cdots \cap \bar{S}_{\gamma}$.

In the cases of $c_{i} \mid$ pipe ${ }_{G}$ and $c_{i} \mid$ pipe ${ }_{I}$ we just use the witness $k=2 n+2$. In the case of $c l_{i} \mid$ forcer we proceed in the same way as in the previous claim. Because $w_{2 n+5} \ldots w_{4 n+7}=a^{2 n+3}$, only the states $q_{\ldots, \ldots}$ can be active within the part $c_{i} \mid$ forcer in time $2 n+6$. The word $w_{2 n+7} \ldots w_{4 n+7}$ maps all such states out of $c l_{i} \mid$ forcer. Each path of length $2 n+2$
leading into $c l_{i} \mid$ forcer from outside starts in $\bar{S}_{2 n+5}$, so it follows that all states from $c_{i} \mid$ forcer lie in $\bar{S}_{4 n+7}$. To handle $t=4 n+8, \ldots, \gamma$ we inductively use the witness $k=1$.
5. Claim: $\left\{c l_{i} \mid v: v \in M_{\phi}\right\} \subseteq \bar{S}_{4 n+8} \cap \cdots \cap \bar{S}_{\gamma}$.

In the cases of $c l_{i} \mid q$ and $c l_{i} \mid q^{\prime}$ we use the witness 1 . We have $w_{4 n+8}=b$ and the only edges labeled by $b$ incoming to remaining states could be some of the $8 m n+4 m$ unspecified edges of $G$. But we have $w_{4 n+6} w_{4 n+7}=a^{2}$, so each out state of any ABS part lies in $\bar{S}_{4 n+7}$ and thus no unspecified edge starts in a state outside $\bar{S}_{4 n+7}$.
6. Claim: cli ${ }_{i}$ pipes $\mathrm{J}_{\mathrm{J}} \cup c l_{i} \mid$ pipes $_{\mathrm{K}} \cup c l_{i} \mid$ pipe $_{\mathrm{D}} \subseteq \bar{S}_{10 n+\alpha_{i}+6} \cap \cdots \cap \bar{S}_{\gamma}$.

We use witnesses $k=\alpha_{i}$ for $c l_{i} \mid$ pipes $_{\mathrm{J}}, k=6 n-2$ for $c l_{i} \mid$ pipes $_{\mathrm{K}}$ and $k=\alpha_{i}+6 n-1$ for $c l_{i} \mid p i p e_{\mathrm{D}}$.
7. Claim: cli $\mid$ limiter $\cup l_{i} \mid$ tester $\subseteq \bar{S}_{16 n+\alpha_{i}+6} \cap \cdots \cap \bar{S}_{\gamma}$.

Because

$$
w_{4 n+\alpha_{i}+9} \ldots w_{10 n+\alpha_{i}+6}=a^{6 n-2},
$$

there are only states of the form $c l_{i} \mid$ limiter $\mid S_{\ldots, 0}$ in the intersection of $c l_{i} \mid$ limiter and $S_{10 n+\alpha_{i}+6}$. Together with the fact that there are only two occurrences of $b$ in $v_{i}$ it confirms that the case of $c l_{i} \mid$ limiter holds. The case of $c l_{i} \mid t e s t e r ~ i s ~ e a s i l y ~$ witnessed by $k=6 n$.
8. Claim: cl $_{i} \mid$ pipe $_{\mathrm{A}} \cup c l_{i} \mid$ pipe $_{\mathrm{E}} \cup c l_{i} \mid$ pipes $_{\mathrm{L}} \subseteq \bar{S}_{\gamma-1} \cap \bar{S}_{\gamma}$.

We use witnesses $k=12 m n+4 n-2 m+6$ for $c l_{i} \mid$ pipe $_{\mathrm{A}}$ and $k=\beta_{i}$ for $c l_{i} \mid$ pipe $_{\mathrm{E}}, c_{i} \mid$ pipes $_{\mathrm{L}}$.
For each $\lambda \in L_{\phi}$ we ensure by the word $u_{i, \lambda}$ that the $\kappa(\lambda)$-th tester column is deactivated in advance, namely at time $t=16 n+\alpha_{i}+5$. The advance allows the following key claim to hold true:

Lemma 2.3. $\left\{c l_{i} \mid \bar{\lambda}: \lambda \in L_{\phi}\right\} \subseteq \bar{S}_{\gamma-1} \cap \bar{S}_{\gamma}$.
Proof. For each such $\lambda$ we choose

$$
k=6 n-3 \kappa(\lambda)+\beta_{i}+1
$$

as a witness of $c l_{i} \mid \bar{\lambda} \in \bar{S}_{\gamma-1}$. There is only one state where a path of length $k$ ending in $\bar{\lambda}$ starts: the state

$$
s=c l_{i} \mid \text { tester } \mid \text { level }_{\lambda} \mid(3, \lambda)
$$

It holds that

$$
s \in \bar{S}_{10 n+\alpha_{i}+3 \kappa(\lambda)+6} \cap \cdots \cap \bar{S}_{\gamma}
$$

as is easily witnessed by $k^{\prime}=3 \kappa(\lambda)$ using Claim 6 of Lemma 2.2. But we are going to show also that

$$
\begin{equation*}
s \in \bar{S}_{10 n+\alpha_{i}+3 \kappa(\lambda)+5} \tag{3}
\end{equation*}
$$

which will imply that $k$ is a true witness of $\bar{\lambda} \in \bar{S}_{\gamma-1}$, because

$$
(\gamma-1)-k=10 n+\alpha_{i}+3 \kappa(\lambda)+5
$$

So let us prove the membership (3). We need to observe, using the definition of $w$, that:

- At time $2 n+5$ the part pipe $_{\mathrm{G}}$ records the sequence

$$
\mathbf{0}, \mathbf{1}, \xi_{1}, \xi_{1}, \xi_{2}, \xi_{2}, \ldots, \xi_{n}, \xi_{n}
$$

and the part pipe ${ }_{\mathrm{I}}$ records the sequence of inverted values. Because

$$
w_{2 n+6} \ldots w_{4 n+7}=a^{2 n+2}
$$

at time $4 n+7$ the states $q, r^{\prime}$ are active, the states $q^{\prime}, r$ are inactive and for each $j \in\{1, \ldots, n\}$ it holds that

$$
x_{j} \in \bar{S}_{4 n+7} \Leftrightarrow y_{j} \in \bar{S}_{4 n+7} \Leftrightarrow \neg x_{j} \in S_{4 n+7} \Leftrightarrow z_{j} \in S_{4 n+7} \Leftrightarrow \xi_{j}=\mathbf{1}
$$

Because $w_{4 n+8}=b$, at time $10 n+\alpha_{i}+6$ we find the whole structure above shifted to the first row of $c_{i} \mid$ tester, so particularly for $\lambda \in L_{\phi}$ :

$$
\operatorname{cl}_{i} \mid \text { tester } \mid \text { level }_{x_{1}} \mid(1, \lambda) \in \bar{S}_{10 n+\alpha_{i}+6} \Leftrightarrow \lambda \text { is satisfied by } \xi_{1}, \ldots, \xi_{n} .
$$

- From a simple induction on tester levels it follows that

$$
c l_{i} \mid \text { tester } \mid \text { level }_{\lambda} \mid(1, r) \in \bar{S}_{10 n+\alpha_{i}+3 \kappa(\lambda)+3} .
$$

Note that

$$
w_{10 n+\alpha_{i}+3 \kappa(\lambda)+4} w_{10 n+\alpha_{i}+3 \kappa(\lambda)+5} w_{10 n+\alpha_{i}+3 \kappa(\lambda)+6}=u_{i, \lambda}
$$

and distinguish the following cases:

- If $\lambda=\bar{\lambda}_{i}$, we have $\lambda \in C_{i}$, the part $c l_{i} \mid$ tester level $\lambda_{\lambda}$ is of type $\operatorname{INC}(\lambda)$ and $u_{i, \lambda}=a^{3}$. We also know that $\lambda$ is satisfied, so

$$
c_{i} \mid \text { tester } \mid \text { level }_{x_{1}} \mid(1, \lambda) \in \bar{S}_{10 n+\alpha_{i}+6}
$$

The state above is the only state, from which any path of length $3 \kappa(\lambda)-3$ leads to $c l_{i} \mid$ tester $\mid$ level $l_{\lambda} \mid(1, \lambda)$, so we deduce that

$$
\text { cl }_{i} \mid \text { tester } \mid \text { level }_{\lambda} \mid(1, \lambda) \in \bar{S}_{10 n+\alpha_{i}+3 \kappa(\lambda)+3}
$$

We see that each path labeled by $a^{2}$ ending in $c l_{i} \mid$ tester $\mid$ level $l_{\lambda} \mid(3, \lambda)$ starts in $c l_{i}|t e s t e r| l e v e l_{\lambda} \mid(1, \lambda)$ or in $c l_{i} \mid$ tester $\mid$ level $_{\lambda} \mid(1, r)$, but each of the two states lies in $\bar{S}_{10 n+\alpha_{i}+3 \kappa(\lambda)+3}$. So the membership (3) holds.

- If $\lambda \notin C$, the part $c l_{i} \mid$ tester level $_{\lambda}$ is of type $\operatorname{NOTINC}(\lambda)$ and $u_{i, \lambda}=a^{3}$. Particularly $w_{10 n+\alpha_{i}+3 \kappa(\lambda)+5}=a$ but no edge labeled by a comes to $c_{i} \mid$ tester $\mid$ level $_{\lambda} \mid(3, \lambda)$ and the membership (3) follows trivially.
- If $\lambda \neq \bar{\lambda}_{i}$ and $\lambda \in C_{i}$, the part $c_{i} \mid$ tester $\mid$ level $_{\lambda}$ is of type INC $(\lambda)$ and $u_{i, \lambda}=b a^{2}$. Particularly

$$
w_{10 n+\alpha_{i}+3 \kappa(\lambda)+4} w_{10 n+\alpha_{i}+3 \kappa(\lambda)+5}=b a,
$$

but no path labeled by ba comes to $c l_{i}|t e s t e r|$ level $l_{\lambda} \mid(3, \lambda)$, so we reach the same conclusion as in the previous case.
We have proven that $c l_{i} \mid \bar{\lambda}$ lies in $\bar{S}_{\gamma-1}$. From Claim 8 of Lemma 2.2 it follows directly that it lies also in $\bar{S}_{\gamma}$.
We see that within $c l_{i}$ only the states from the ABS parts can lie in $S_{\gamma-1}$. Since $w_{\gamma-2} w_{\gamma-1}=a^{2}$, no state $r_{1}$, $r_{2}$ nor out from any ABS part lies in $S_{\gamma-1}$. Now we easily check that all the states possibly present in $S_{\gamma-1}$ are mapped to $s_{2}$ by the word $w_{\gamma} \ldots w_{d}=b^{2} a b^{4 n+m+7}$.

### 2.4. From a word to an assignment

From now on we suppose that there is a reset word $w$ of length

$$
d=12 m n+8 n-m+18
$$

The following lemma is not hard to verify:

## Lemma 2.4.

1. Up to labeling there is a unique pair of paths, both of a length $l \leq d-2$, leading from $c l_{1}\left|p i p e_{\mathrm{A}}\right| s_{1}$ and $c l_{2}\left|p i p e_{\mathrm{A}}\right| s_{1}$ to a common end. They are of length $d-2$ and meet in $s_{2}$.
2. The word $w$ starts by $a^{2}$.

Proof. 1. The leading segments of both paths are similar since they stay within the parts $c l_{1}$ and $c l_{2}$ :

$$
\begin{aligned}
\operatorname{pipe}_{\mathrm{A}} \mid s_{1} \xrightarrow{a, b} \ldots & \xrightarrow{a, b} p i p e_{\mathrm{A}}\left|s_{12 m n+4 n-2 m+6} \xrightarrow{a, b} a b s_{1}\right| i n \xrightarrow{b} \\
& \xrightarrow{b} a b s_{1}\left|r_{1} \xrightarrow{b} a b s_{1}\right| \text { out } \xrightarrow{a} s p_{1} \xrightarrow{b} \ldots \xrightarrow{b} s p_{4 n+6} .
\end{aligned}
$$

Once the paths leave the parts $c l_{1}$ and $c l_{2}$, the shortest way to merge is the following:

$$
\begin{aligned}
& c l_{1} \mid s p_{4 n+6} \\
& c l_{2} \mid s p_{4 n+6} \\
& \xrightarrow{b} q_{1} \xrightarrow{b} q_{2} \xrightarrow{b} q_{2} \xrightarrow{b} \ldots \xrightarrow{b} \ldots \xrightarrow{b} q_{m-1} \xrightarrow{b} q_{m} \xrightarrow{b} s_{1} \xrightarrow{b} s_{2} \\
& \xrightarrow{b} s_{1} \xrightarrow{b} s_{2} \xrightarrow{b} s_{2}
\end{aligned}
$$

Having the description above it is easy to verify that the length is $d-2$ and there is no way to make the paths shorter.
2. Suppose that $w_{1} w_{2} \neq a^{2}$. Any of the three possible values of $w_{1} w_{2}$ implies that

$$
\left\{c l_{i}\left|s p_{3}, \ldots, c l_{i}\right| s p_{4 n+6}\right\} \subseteq S_{2}
$$

for each $i$. It cannot hold that $w=w_{1} w_{2} b^{d-2}$, because in such case all $c l \ldots|c c a| s_{b}$ states would be active in any time $t \geq 3$. So the word $w$ has a prefix $w_{1} w_{2} b^{k} a$ for some $k \geq 0$. If $k \leq 4 n+3$, it holds that $c l_{i} \mid s p_{4 n+6} \in S_{k+2}$ and therefore
$c l_{i} \mid$ pipe $_{\mathrm{A}} \mid s_{1} \in S_{k+3}$, which contradicts the first claim. Let $k \geq 4 n+4$. Some state of the form $c l_{i} \mid$ forcer $\mid q_{1, \ldots}$ or $c l_{i} \mid$ forcer $\mid r_{1, \ldots}$ lies in $S_{k+2}$ for each $i$. This holds particularly for $i=1$ and $i=2$, but there is no pair of paths of length at most

$$
d-(4 n+4) \geq d-k
$$

leading from such two states to a common end.
The second claim implies that $c l_{i} \mid$ pipe ${ }_{\mathrm{A}} \mid s_{1} \in S_{2}$ for each $i \in\{1, \ldots, m\}$, so it follows that

$$
\delta(Q, w)=\left\{s_{2}\right\}
$$

Let us denote

$$
\begin{aligned}
\bar{d} & =12 m n+4 n-2 m+11, \\
\bar{w} & =w_{1} \ldots w_{\bar{d}}
\end{aligned}
$$

and

$$
S^{\prime}=\left\{s \in Q \mid(\exists d \in \mathbb{N}) \delta\left(s, b^{d}\right)=s_{2}\right\} .
$$

The following lemma holds because no edges labeled by $a$ are available for final segments of the paths described in the first claim of Lemma 2.4:

## Lemma 2.5.

1. The word $w$ can be written as $w=\bar{w} b^{4 n+m+7}$ for some word $\bar{w}$.
2. For any $t \geq \bar{d}$, no state from any $c l \ldots$... part lies in $S_{t}$, except for the $s p$... states.

Proof. 1. Let us write $w=w_{1} w_{2} w^{\prime}$. From Lemma 2.4 it follows that

$$
\delta\left(c l_{1}\left|p i p e_{\mathrm{A}}\right| s_{1}, w^{\prime}\right)=\delta\left(c l_{2}\left|p i p e_{\mathrm{A}}\right| s_{1}, w^{\prime}\right)
$$

and $w^{\prime}$ has to label some of the paths determined up to the labeling in Lemma 2.4(1). The final $4 n+m+7$ edges of the paths lead from $c l_{1} \mid s p_{1}$ and $c l_{2} \mid s p_{1}$ to $s_{2}$. All the transitions used here are necessarily labeled by $b$.
2. The claim is easy to observe, since the first claim implies that $S_{t}$ is a subset of $S^{\prime}$.

The next lemma is based on properties of the parts $c l \ldots \mid$ forcer but to prove that no more $a$ follows the enforced factor $a^{2 n+1}$ we also need to observe that each $c l \ldots|c c a|$ out or each $c l \ldots|c c i| o u t$ lies in $S_{2 n+4}$ :

Lemma 2.6. The word $\bar{w}$ starts by $\bar{u} a^{2 n+1}$ b for some $\bar{u}$ of length $2 n+6$.
Proof. At first we prove that $\bar{w}$ starts by $\bar{u} a^{2 n+1}$. Lemma 2.4(2) implies that $c l_{1}\left|p i p e_{B}\right| s_{1} \in S_{2}$, so obviously at least one of the states $c l_{1} \mid$ forcer $\mid q_{1,0}$ and $c l_{1} \mid$ forcer $\mid r_{1,0}$ lies in $S_{2 n+6}$. If $w_{2 n+6+k}=b$ for some $k \in\{1, \ldots, 2 n+1\}$, it holds that $c l_{i} \mid$ forcer $\mid q_{k, 2}$ or $c l_{i} \mid$ forcer $\mid r_{k, 2}$ lies in $S_{2 n+6+k}$. From such a state no path of length at most $2 n+3-k$ leads to $c l_{i}\left|p i p e_{\mathrm{D}}\right| s_{1}$ and therefore no path of length at most

$$
(2 n+3-k)+\left(\alpha_{i}+6 n-1\right)+(6 n-2)+\beta_{i}+3=\bar{d}-(2 n+6+k)
$$

leads into $S^{\prime}$, which contradicts Lemma 2.5(2). It remains to show that there is $b$ after the prefix $\bar{u} a^{2 n+1}$. Lemma 2.4(2) implies that both $c l_{1}|c c a|$ in and $c l_{1}|c c i|$ in lie in $S_{2 n+1}$, from which it is not hard to deduce that $c l_{1}|c c a| o u t$ or $c l_{1}|c c i|$ out lies in $S_{2 n+4}$ and therefore $c l_{1} \mid q$ or $c l_{1} \mid r$ lies in $S_{4 n+7}$. Any path of length $\bar{d}-(4 n+7)$ leading from $c l_{1} \mid q$ or $c l_{1} \mid r$ into $\bar{S}$ starts by an edge labeled by $b$.

Now we are able to write the word $\bar{w}$ as

$$
\bar{w}=\bar{u} a^{2 n+1} b\left(\bar{v}_{1} v_{1}^{\prime} c_{1}\right) \ldots\left(\bar{v}_{m} v_{m}^{\prime} c_{m}\right) w_{\bar{d}-2} w_{\bar{d}-1} w_{\bar{d}},
$$

where $\left|\bar{v}_{k}\right|=6 n-2,\left|v_{k}^{\prime}\right|=6 n-1$ and $\left|c_{k}\right|=1$ for each $k$ and denote $d_{i}=10 n+\alpha_{i}+6$. At time $2 n+5$ the parts $c l \ldots$... $\mid p i p e_{G}$ and $c l \ldots \mid$ pipe ${ }_{\mathrm{I}}$ record mutually inverse sequences. The factor $a^{2 n+1} b$ after $\bar{u}$ guarantees that at time $d_{i}$ we find the information pushed to the first rows of testers:

Lemma 2.7. For each $i \in\{1, \ldots, m\}, j \in\{1, \ldots, n\}$ it holds that

$$
\begin{aligned}
c l_{i} \mid \text { tester } \mid \text { level }_{x_{1}} \mid\left(1, x_{j}\right) & \in S_{d_{i}} \Leftrightarrow \\
\text { cl }_{i} \mid \text { tester } \mid \text { level }_{x_{1}} \mid\left(1, \neg x_{j}\right) & \notin S_{d_{i}} \Leftrightarrow w_{2 n-2 j+2} \neq w_{2 n-2 j+3} .
\end{aligned}
$$

Proof. From the definition of CCA and CCI it follows that at time $2 n+5$ the parts pipe $_{G}$ and pipe ${ }_{I}$ record the sequences $B_{(2 n+3)} \ldots B_{(2)}$ and $B_{(2 n+3)}^{\prime} \ldots B_{(2)}^{\prime}$ respectively, where

$$
B_{(k)}=\left\{\begin{array}{ll}
\mathbf{1} & \text { if } w_{k}=w_{k+1}, \\
\mathbf{0} & \text { otherwise },
\end{array} \quad B_{(k)}^{\prime}= \begin{cases}\mathbf{0} & \text { if } w_{k}=w_{k+1}, \\
\mathbf{1} & \text { otherwise }\end{cases}\right.
$$

Whatever the letter $w_{2 n+6}$ is, Lemma 2.6 implies that

$$
c l_{i}\left|x_{j} \in S_{4 n+7} \Leftrightarrow c l_{i}\right| \neg x_{j} \notin S_{4 n+7} \Leftrightarrow w_{2 n-2 j+2} \neq w_{2 n-2 j+3},
$$

from which the claim follows easily according to the shape of $c l_{i} \mid p i p e s_{\mathrm{J}}$ and $c l_{i} \mid \operatorname{pipes}_{\mathrm{K}}$.

Let us define the assignment $\xi_{1}, \ldots, \xi_{n} \in\{\mathbf{0}, \mathbf{1}\}$ :

$$
\xi_{j}= \begin{cases}\mathbf{1} & \text { if } w_{2 n-2 j+2}=w_{2 n-2 j+3} \\ \mathbf{0} & \text { otherwise }\end{cases}
$$

Note that the definition may be directly rephrased according to Lemma 2.7. The following lemma holds due to the $c l$... $\mid$ limiter parts:

Lemma 2.8. For each $i \in\{1, \ldots, m\}$ there are at most two occurrences of $b$ in the word $v_{i}^{\prime}$.
Proof. It is easy to see that $c l_{i} \mid$ limiter $\mid s_{1,0} \in S_{10 n+\alpha_{i}+6}$ and to note that

$$
v_{i}^{\prime}=w_{10 n+\alpha_{i}+7} \ldots w_{16 n+\alpha_{i}+5}
$$

Within the part $c l_{i} \mid$ limiter no state except for $S_{6 n-2,0}$ can lie in $S_{16 n+\alpha_{i}+5}$, because from such states there is no path of length at most

$$
\bar{d}-\left(16 n+\alpha_{i}+5\right)=\beta_{i}+4
$$

leading into $S^{\prime}$.
The shortest paths from $s_{1,0}$ to $s_{6 n-2,0}$ have length $6 n-3$ and each path from $s_{1,0}$ into $S^{\prime}$ uses the state $s_{6 n-2,0}$. So there is a path $P$ leading from $s_{1,0}$ to $s_{6 n-2,0}$ labeled by a prefix of $v^{\prime}$. We distinguish the following cases:

- If $P$ is of length $6 n-3$, we just note that such path is unique and labeled by $a^{6 n-3}$. No $b$ occurs in $v^{\prime}$ except for the last two positions.
- If $P$ is of length $6 n-2$, it uses an edge of the form $s_{k, 0} \xrightarrow{b} s_{k+1,1}$. Such edges preserve the distance to $s_{6 n-2}$, so the rest of $P$ must be a shortest path from $s_{k+1,1}$ to $s_{6 n-2,0}$. Such paths are unique and labeled by $a^{6 n-2-k}$. Any other $b$ can occur only at the last position.
- If $P$ is of length $6 n-1$, it is labeled by whole $v^{\prime}$. Because any edge labeled by $b$ preserves or increases the distance to $s_{6 n-2}$, the path $P$ can use at most two of them.

Now we choose any $i \in\{1, \ldots, m\}$ and prove that the assignment $\xi_{1}, \ldots, \xi_{n}$ satisfies the clause $\bigvee_{\lambda \in C_{i}} \lambda$. Let $p \in\{0,1,2,3\}$ denote the number of unsatisfied literals in $C_{i}$.

As we claimed before, all tester columns corresponding to any $\lambda \in L_{\phi}$ have to be deactivated earlier than other columns. Namely, if $c l_{i} \mid$ tester $\mid$ level $_{x_{1}} \mid(1, \lambda)$ is active at time $d_{i}$, which happens if and only if $\lambda$ is not satisfied by $\xi_{1}, \ldots, \xi_{n}$, the word $v_{i}^{\prime} c_{i}$ must not map it to $c_{i} \mid$ pipes $_{L} \mid s_{1, \mu(\lambda)}$. If $c l_{i} \mid$ tester $\mid$ level $l_{\lambda}$ is of type $\operatorname{INC}(\lambda)$, the only way to ensure this is to use the letter $b$ when the border of inactive area lies at the first row of $c l_{i}|t e s t e r|$ level $l_{\lambda}$. Thus each unsatisfied $\lambda \in C_{i}$ implies an occurrence of $b$ in corresponding segment of $v_{i}^{\prime}$ :

Lemma 2.9. There are at least $p$ occurrences of the letter $b$ in the word $v_{i}^{\prime}$.

Proof. Let $\lambda_{1}, \ldots, \lambda_{p}$ be the unsatisfied literals of $C_{i}$. From Lemma 2.7 it follows easily that

$$
\text { cl }_{i} \mid \text { tester } \mid \text { level }_{\lambda_{k}} \mid\left(1, \lambda_{k}\right) \in S_{d_{i}+3 \kappa\left(\lambda_{k}\right)}
$$

for each $k \in\{1, \ldots, p\}$. The part $c l_{i} \mid$ tester $\mid$ level $l_{\lambda_{k}}$ is of type $\operatorname{INC}\left(\lambda_{k}\right)$, which implies that any path of the length

$$
(\bar{d}-3)-\left(d_{i}+3 \kappa\left(\lambda_{k}\right)\right)
$$

starting by a takes $c l_{i} \mid$ tester $\mid$ level $\lambda_{\lambda_{k}} \mid\left(1, \lambda_{k}\right)$ to the state $c l_{i} \mid \bar{\lambda}$, which lies outside $S_{\bar{d}-3}$, as it is implied by Lemma 2.5(2). We deduce that $w_{d_{i}+3 \kappa\left(\lambda_{k}\right)+1}=b$.

By Lemma 2.8 there are at most two occurrences of $b$ in $v_{i}^{\prime}$, so we get $p \leq 2$ and there is at least one satisfied literal in $C_{i}$.
