## Jirka Fink: Optimization methods

### General information

E-mail [fink@ktiml.mff.cuni.cz](mailto:fink@ktiml.mff.cuni.cz)  
 Homepage <https://ktiml.mff.cuni.cz/~fink/>  
 Consultations Individual schedule

### Examination

- Tutorial conditions
  - Tests
  - Theoretical homeworks
  - Practical homeworks
- Pass the exam

## Outline

- Linear programming
- Linear, affine and convex sets
- Convex polyhedron
- Simplex method
- Duality of linear programming
- Ellipsoid method
- Matching

## Matrix notation of the linear programming problem

### Formulation using linear programming

$$\begin{array}{ll} \text{Minimize} & 0.75x_1 + 0.5x_2 + 0.15x_3 \\ \text{subject to} & \begin{array}{l} 35x_1 + 0.5x_2 + 0.5x_3 \geq 0.5 \\ 60x_1 + 300x_2 + 10x_3 \geq 15 \\ 30x_1 + 20x_2 + 10x_3 \geq 4 \\ x_1, x_2, x_3 \geq 0 \end{array} \end{array}$$

### Matrix notation

- Minimize  $\begin{pmatrix} 0.75 \\ 0.5 \\ 0.15 \end{pmatrix}^T \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$
- Subject to  $\begin{pmatrix} 35 & 0.5 & 0.5 \\ 60 & 300 & 10 \\ 30 & 20 & 10 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \geq \begin{pmatrix} 0.5 \\ 15 \\ 4 \end{pmatrix}$
- and  $x_1, x_2, x_3 \geq 0$

### Plan of the lecture

- Linear and integer optimization
- Convex sets and Minkowski-Weyl theorem
- Simplex methods
- Duality of linear programming
- Ellipsoid method
- Unimodularity
- Minimal weight maximal matching
- Matroid
- Cut and bound method

## Example of linear programming: Optimized diet

### Express using linear programming the following problem

Find the cheapest vegetable salad from carrots, white cabbage and cucumbers containing required amount the vitamins A and C and dietary fiber.

Food	Carrot	White cabbage	Cucumber	Required per meal
Vitamin A [mg/kg]	35	0.5	0.5	0.5 mg
Vitamin C [mg/kg]	60	300	10	15 mg
Dietary fiber [g/kg]	30	20	10	4 g
Price [EUR/kg]	0.75	0.5	0.15	

### Formulation using linear programming

$$\begin{array}{llllll} & \text{Carrot} & & \text{White cabbage} & & \text{Cucumber} & & & & \\ \text{Minimize} & 0.75x_1 & + & 0.5x_2 & + & 0.15x_3 & & & & \text{Cost} \\ \text{subject to} & 35x_1 & + & 0.5x_2 & + & 0.5x_3 & \geq & 0.5 & & \text{Vitamin A} \\ & 60x_1 & + & 300x_2 & + & 10x_3 & \geq & 15 & & \text{Vitamin C} \\ & 30x_1 & + & 20x_2 & + & 10x_3 & \geq & 4 & & \text{Dietary fiber} \\ & & & & & x_1, x_2, x_3 & \geq & 0 & & \end{array}$$

## Notation: Vector and matrix

### Scalar

A scalar is a real number. Scalars are written as  $a, b, c$ , etc.

### Vector

A vector is an  $n$ -tuple of real numbers. Vectors are written as  $\mathbf{c}, \mathbf{x}, \mathbf{y}$ , etc. Usually, vectors are column matrices of type  $n \times 1$ .

### Matrix

A matrix of type  $m \times n$  is a rectangular array of  $m$  rows and  $n$  columns of real numbers. Matrices are written as  $A, B, C$ , etc.

### Special vectors

$\mathbf{0}$  and  $\mathbf{1}$  are vectors of zeros and ones, respectively.

### Transpose

The transpose of a matrix  $A$  is matrix  $A^T$  created by reflecting  $A$  over its main diagonal. The transpose of a column vector  $\mathbf{x}$  is the row vector  $\mathbf{x}^T$ .

Elements of a vector and a matrix

- The  $i$ -th element of a vector  $\mathbf{x}$  is denoted by  $x_i$ .
- The  $(i, j)$ -th element of a matrix  $A$  is denoted by  $A_{i,j}$ .
- The  $i$ -th row of a matrix  $A$  is denoted by  $A_{i,*}$ .
- The  $j$ -th column of a matrix  $A$  is denoted by  $A_{*,j}$ .

Dot product of vectors

The dot product (also called inner product or scalar product) of vectors  $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$  is the scalar  $\mathbf{x}^T \mathbf{y} = \sum_{i=1}^n x_i y_i$ .

Product of a matrix and a vector

The product  $A\mathbf{x}$  of a matrix  $A \in \mathbb{R}^{m \times n}$  of type  $m \times n$  and a vector  $\mathbf{x} \in \mathbb{R}^n$  is a vector  $\mathbf{y} \in \mathbb{R}^m$  such that  $y_i = A_{i,*} \mathbf{x}$  for all  $i = 1, \dots, m$ .

Product of two matrices

The product  $AB$  of a matrix  $A \in \mathbb{R}^{m \times n}$  and a matrix  $B \in \mathbb{R}^{n \times k}$  a matrix  $C \in \mathbb{R}^{m \times k}$  such that  $C_{*,j} = AB_{*,j}$  for all  $j = 1, \dots, k$ .

Optimization

Mathematical optimization

Mathematical optimization is the selection of a best element (with regard to some criteria) from some set of available alternatives.

Examples

- Minimize  $x^2 + y^2$  where  $(x, y) \in \mathbb{R}^2$
- Maximal matching in a graph
- Minimal spanning tree
- Shortest path between given two vertices

Optimization problem

Given a set of solutions  $M$  and an objective function  $f : M \rightarrow \mathbb{R}$ , optimization problem is finding a solution  $x \in M$  with the maximal (or minimal) objective value  $f(x)$  among all solutions of  $M$ .

Duality between minimization and maximization

If  $\min_{x \in M} f(x)$  exists, then also  $\max_{x \in M} -f(x)$  exists and  $-\min_{x \in M} f(x) = \max_{x \in M} -f(x)$ .

Terminology

Basic terminology

- Number of variables:  $n$
- Number of constrains:  $m$
- Solution: an arbitrary vector  $\mathbf{x}$  of  $\mathbb{R}^n$
- Objective function: a function to be minimized or maximized, e.g.  $\max \mathbf{c}^T \mathbf{x}$
- Feasible solution: a solution satisfying all constrains, e.g.  $A\mathbf{x} \leq \mathbf{b}$
- Optimal solution: a feasible solution maximizing  $\mathbf{c}^T \mathbf{x}$
- Infeasible problem: a problem having no feasible solution
- Unbounded problem: a problem having a feasible solution with arbitrary large value of given objective function
- Polyhedron: a set of points  $\mathbf{x} \in \mathbb{R}^n$  satisfying  $A\mathbf{x} \leq \mathbf{b}$  for some  $A \in \mathbb{R}^{m \times n}$  and  $\mathbf{b} \in \mathbb{R}^m$
- Polytope: a bounded polyhedron

Graphical method: Set of feasible solutions

Example

Draw the set of all feasible solutions  $(\mathbf{x}_1, \mathbf{x}_2)$  satisfying the following conditions.

$$\begin{aligned} x_1 + 6x_2 &\leq 15 \\ 4x_1 - x_2 &\leq 10 \\ -x_1 + x_2 &\leq 1 \\ x_1, x_2 &\geq 0 \end{aligned}$$

Solution

Equality and inequality of two vectors

For vectors  $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$  we denote

- $\mathbf{x} = \mathbf{y}$  if  $x_i = y_i$  for every  $i = 1, \dots, n$  and
- $\mathbf{x} \leq \mathbf{y}$  if  $x_i \leq y_i$  for every  $i = 1, \dots, n$ .

System of linear equations

Given a matrix  $A \in \mathbb{R}^{m \times n}$  of type  $m \times n$  and a vector  $\mathbf{b} \in \mathbb{R}^m$ , the formula  $A\mathbf{x} = \mathbf{b}$  means a system of  $m$  linear equations where  $\mathbf{x}$  is a vector of  $n$  real variables.

System of linear inequalities

Given a matrix  $A \in \mathbb{R}^{m \times n}$  of type  $m \times n$  and a vector  $\mathbf{b} \in \mathbb{R}^m$ , the formula  $A\mathbf{x} \leq \mathbf{b}$  means a system of  $m$  linear inequalities where  $\mathbf{x}$  is a vector of  $n$  real variables.

Example: System of linear inequalities in two different notations

$$\begin{aligned} 2x_1 + x_2 + x_3 &\leq 14 \\ 2x_1 + 5x_2 + 5x_3 &\leq 30 \end{aligned} \quad \begin{pmatrix} 2 & 1 & 1 \\ 2 & 5 & 5 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \leq \begin{pmatrix} 14 \\ 30 \end{pmatrix}$$

Linear Programming

Linear programming problem

A linear program is the problem of maximizing (or minimizing) a given linear function over the set of all vectors that satisfy a given system of linear equations and inequalities.

Equation form:  $\min \mathbf{c}^T \mathbf{x}$  subject to  $A\mathbf{x} = \mathbf{b}, \mathbf{x} \geq \mathbf{0}$

Canonical form:  $\max \mathbf{c}^T \mathbf{x}$  subject to  $A\mathbf{x} \leq \mathbf{b}$ ,

where  $\mathbf{c} \in \mathbb{R}^n, \mathbf{b} \in \mathbb{R}^m, A \in \mathbb{R}^{m \times n}$  and  $\mathbf{x} \in \mathbb{R}^n$ .

Conversion from the equation form to the canonical form

$\max -\mathbf{c}^T \mathbf{x}$  subject to  $A\mathbf{x} \leq \mathbf{b}, -A\mathbf{x} \leq -\mathbf{b}, -\mathbf{x} \leq \mathbf{0}$

Conversion from the canonical form to the equation form

$\min -\mathbf{c}^T \mathbf{x}' + \mathbf{c}^T \mathbf{x}''$  subject to  $A\mathbf{x}' - A\mathbf{x}'' + I\mathbf{x}''' = \mathbf{b}, \mathbf{x}', \mathbf{x}'', \mathbf{x}''' \geq \mathbf{0}$

Example of linear programming: Network flow

Network flow problem

Given a directed graph  $(V, E)$  with capacities  $\mathbf{c} \in \mathbb{R}^E$  and a source  $s \in V$  and a sink  $t \in V$ , find the maximal flow from  $s$  to  $t$  satisfying the flow conservation and capacity constrains.

Formulation using linear programming

Variables: Flow  $x_e$  for every edge  $e \in E$

Capacity constrains:  $0 \leq x_e \leq c_e$

Flow conservation:  $\sum_{uv \in E} x_{uv} = \sum_{vw \in E} x_{vw}$  for every  $v \in V \setminus \{s, t\}$

Objective function: Maximize  $\sum_{sw \in E} x_{sw} - \sum_{us \in E} x_{us}$

Matrix notation

- Add an auxiliary edge  $x_{ts}$  with a sufficiently large capacity  $c_{ts}$

Objective function:  $\max \mathbf{x}_{ts}$

Flow conservation:  $A\mathbf{x} = \mathbf{0}$  where  $A$  is the incidence matrix

Capacity constrains:  $\mathbf{x} \leq \mathbf{c}$  and  $\mathbf{x} \geq \mathbf{0}$

Graphical method: Optimal solution

Example

Find the optimal solution of the following problem.

$$\begin{aligned} \text{Maximize } x_1 + x_2 \\ x_1 + 6x_2 &\leq 15 \\ 4x_1 - x_2 &\leq 10 \\ -x_1 + x_2 &\leq 1 \\ x_1, x_2 &\geq 0 \end{aligned}$$

Solution

## Graphical method: Multiple optimal solutions

### Example

Find all optimal solutions of the following problem.

$$\begin{aligned} \text{Maximize} \quad & \frac{1}{6}x_1 + x_2 \\ & x_1 + 6x_2 \leq 15 \\ & 4x_1 - x_2 \leq 10 \\ & -x_1 + x_2 \leq 1 \\ & x_1, x_2 \geq 0 \end{aligned}$$

### Solution

## Graphical method: Unbounded problem

### Example

Show that the following problem is unbounded.

$$\begin{aligned} \text{Maximize} \quad & x_1 + x_2 \\ & -x_1 + x_2 \leq 1 \\ & x_1, x_2 \geq 0 \end{aligned}$$

### Solution

## Graphical method: Infeasible problem

### Example

Show that the following problem has no feasible solution.

$$\begin{aligned} \text{Maximize} \quad & x_1 + x_2 \\ & x_1 + x_2 \leq -2 \\ & x_1, x_2 \geq 0 \end{aligned}$$

### Solution

## Related problems

### Integer linear programming

Integer linear programming problem is an optimization problem to find  $x \in \mathbb{Z}^n$  which maximizes  $c^T x$  and satisfies  $Ax \leq b$  where  $A \in \mathbb{R}^{m \times n}$  and  $b \in \mathbb{R}^m$ .

### Mix integer linear programming

Some variables are integer and others are real.

### Binary linear programming

Every variable is either 0 or 1.

### Complexity

- A linear programming problem is efficiently solvable, both in theory and in practice.
- The classical algorithm for linear programming is the *Simplex method* which is fast in practice but it is not known whether it always run in polynomial time.
- Polynomial time algorithms are *ellipsoid* and *interior point* methods.
- No strongly polynomial-time algorithms for linear programming is known.
- Integer linear programming is NP-hard.

## Example of integer linear programming: Vertex cover

### Vertex cover problem

Given an undirected graph  $(V, E)$ , find the smallest set of vertices  $U \subseteq V$  covering every edge of  $E$ ; that is,  $U \cup e \neq \emptyset$  for every  $e \in E$ .

### Formulation using integer linear programming

Variables: Cover  $x_v \in \{0, 1\}$  for every vertex  $v \in V$

Covering:  $x_u + x_v \geq 1$  for every edge  $uv \in E$

Objective function: Minimize  $\sum_{v \in V} x_v$

### Matrix notation

Variables: Cover  $x \in \{0, 1\}^V$  (i.e.  $0 \leq x \leq 1$  and  $x \in \mathbb{Z}^V$ )

Covering:  $A^T x \geq 1$  where  $A$  is the incidence matrix

Objective function: Minimize  $1^T x$

## Example: Ice cream production planning

### Problem description

- An ice cream manufacturer needs to plan production of ice cream for next year
- The estimated demand of ice cream for month  $i \in \{1, \dots, n\}$  is  $d_i$  (in tons)
- Price for storing ice cream is a per ton and month
- Changing the production by 1 ton from month  $i-1$  to month  $i$  cost  $b$
- Produced ice cream cannot be stored longer than one month
- The total cost has to be minimized

## Relation between optimal integer and relaxed solution

### Non-empty polyhedron may not contain an integer solution

### Integer feasible solution may not be obtained by rounding of a relaxed solution

## Example: Ice cream production planning

### Solution

- 1 Variable  $x_i$  determines the amount of produced ice cream in month  $i \in \{0, \dots, n\}$
- 2 Variable  $s_i$  determines the amount of stored ice cream from month  $i-1$  month  $i$
- 3 The stored quantity is computed by  $s_i = s_{i-1} + x_i - d_i$  for every  $i \in \{1, \dots, n\}$
- 4 Durability is ensured by  $s_i \leq d_i$  for all  $i \in \{1, \dots, n\}$
- 5 Non-negativity of the production and the storage  $x, s \geq 0$
- 6 Objective function  $\min b \sum_{i=1}^n |x_i - x_{i-1}| + a \sum_{i=1}^n s_i$  is non-linear
- 7 We introduce variables  $y_i$  for  $i \in \{1, \dots, n\}$  to avoid the absolute value
- 8 Linear programming problem formulation

$$\begin{aligned} \text{Minimize} \quad & b \sum_{i=1}^n y_i + a \sum_{i=1}^n s_i \\ \text{subject to} \quad & s_{i-1} - s_i + x_i = d_i \quad \text{for } i \in \{1, \dots, n\} \\ & s_i \leq d_i \quad \text{for } i \in \{1, \dots, n\} \\ & x_i - x_{i-1} - y_i \leq 0 \quad \text{for } i \in \{1, \dots, n\} \\ & -x_i + x_{i-1} - y_i \leq 0 \quad \text{for } i \in \{1, \dots, n\} \\ & x, s, y \geq 0 \end{aligned}$$

- 9 We can bound the initial and final amount of ice cream  $s_0$  a  $s_n$
- 10 and also bound the production  $x_0$

Shortest path problem

Given an oriented graph  $(V, E)$  with length of edges  $c \in \mathbb{Z}^n$  and a starting vertex  $s$ , find the length of a shortest path from  $s$  to all vertices.

Linear programming problem

$$\begin{aligned} & \text{Maximize} && \sum_{u \in V} x_u \\ & \text{subject to} && x_v - x_u \leq c_{uv} \text{ for every edge } uv \\ & && x_s = 0 \end{aligned}$$

Proof (optimal solution  $x_u^*$  of LP gives the distance from  $s$  to  $u$  for  $\forall u \in V$ )

- 1 Let  $y_u$  be the length of a shortest path from  $s$  to  $u$
- 2 It holds that  $y \geq x^*$ 
  - Let  $P$  be edges on the shortest path from  $s$  to  $z$
  - $y_z = \sum_{uv \in P} c_{uv} \geq \sum_{uv \in P} x_v^* - x_u^* = x_z^* - y_s^* = x_z^*$
- 3 It holds that  $y = x^*$ 
  - For the sake of contradiction assume that  $y \neq x^*$
  - So  $y \geq x^*$  and  $\sum_{u \in V} y_u > \sum_{u \in V} x_u^*$
  - But  $y$  is a feasible solution and  $x^*$  is an optimal solution

Linear space

Definition: Linear (vector) space

A set  $(V, +, \cdot)$  is called a linear (vector) space over a field  $T$  if

- $+$ :  $V \times V \rightarrow V$  i.e.  $V$  is closed under addition  $+$
- $\cdot$ :  $T \times V \rightarrow V$  i.e.  $V$  is closed under multiplication by  $T$
- $(V, +)$  is an Abelian group
- For every  $x \in V$  it holds that  $1 \cdot x = x$  where  $1 \in T$
- For every  $a, b \in T$  and every  $x \in V$  it holds that  $(ab) \cdot x = a \cdot (b \cdot x)$
- For every  $a, b \in T$  and every  $x \in V$  it holds that  $(a + b) \cdot x = a \cdot x + b \cdot x$
- For every  $a \in T$  and every  $x, y \in V$  it holds that  $a \cdot (x + y) = a \cdot x + a \cdot y$

Observation

If  $V$  is a linear space and  $L \subseteq V$ , then  $L$  is a linear space if and only if

- $0 \in L$ ,
- $x + y \in L$  for every  $x, y \in L$  and
- $\alpha x \in L$  for every  $x \in L$  and  $\alpha \in T$ .

- 1 By definition,  $L = V + a$  for some linear space  $V$  and some vector  $a \in \mathbb{R}^n$ . Observe that  $L - x = V + (a - x)$  and we prove that  $V + (a - x) = V$  which implies that  $L - x$  is a linear space. There exists  $y \in V$  such that  $x = y + a$ . Hence,  $a - x = a - y - a = -y \in V$ . Since  $V$  is closed under addition, it follows that  $V + (a - x) \subseteq V$ . Similarly,  $V - (a - x) \subseteq V$  which implies that  $V \subseteq V + (a - x)$ . Hence,  $V = V + (a - x)$  and the statement follows.
- 2 We proved that  $L = V + a$  for some linear space  $V \subseteq \mathbb{R}^n$  and some vector  $a \in \mathbb{R}^n$  and  $L - x = V + (a - x) = V$  for every  $x \in L$ . So,  $L - x = V = L - y$ .
- 3 Every linear space must contain the origin by definition. For the opposite implication, we set  $x = 0$  and apply the previous statement.
- 4 If  $V$  is a linear space, then we can obtain rows of  $A$  from the basis of the orthogonal space of  $V$ .
- 5 If  $L$  is an affine space, then  $L = V + a$  for some vector space  $V$  and some vector  $a$  and there exists a matrix  $A$  such that  $V = \{x; Ax = 0\}$ . Hence,  $V + a = \{x + a; Ax = 0\} = \{y; Ay - Aa = 0\} = \{y; Ay = b\}$  where we substitute  $x + a = y$  and set  $b = Aa$ . If  $L = \{x; Ax = b\}$  is non-empty, then let  $y$  be an arbitrary vertex of  $L$ . Furthermore,  $L - y = \{x - y; Ax = b\} = \{z; Ay + Az = b\} = \{z; Az = 0\}$  is a linear space since  $Ay = b$ .

Linear, affine and convex hulls

Observation

- The intersection of linear spaces is also a linear space. ①
- The non-empty intersection of affine spaces is an affine space. ②
- The intersection of convex sets is also a convex set. ③

Definition

Let  $S \subseteq \mathbb{R}^n$  be a non-empty set.

- The *linear hull*  $\text{span}(S)$  of  $S$  is the intersection of all linear sets containing  $S$ .
- The *affine hull*  $\text{aff}(S)$  of  $S$  is the intersection of all affine sets containing  $S$ .
- The *convex hull*  $\text{conv}(S)$  of  $S$  is the intersection of all convex sets containing  $S$ .

Observation

Let  $S \subseteq \mathbb{R}^n$  be a non-empty set.

- A set  $S$  is linear if and only if  $S = \text{span}(S)$ . ④
- A set  $S$  is affine if and only if  $S = \text{aff}(S)$ . ⑤
- A set  $S$  is convex if and only if  $S = \text{conv}(S)$ . ⑥
- $\text{span}(S) = \text{aff}(S \cup \{0\})$

- 1 Linear programming
- 2 Linear, affine and convex sets
- 3 Convex polyhedron
- 4 Simplex method
- 5 Duality of linear programming
- 6 Ellipsoid method
- 7 Matching

Linear and affine spaces in  $\mathbb{R}^n$

Observation

A non-empty set  $V \subseteq \mathbb{R}^n$  is a linear space if and only if  $\alpha x + \beta y \in V$  for all  $\alpha, \beta \in \mathbb{R}$ ,  $x, y \in V$ .

Definition

If  $V \subseteq \mathbb{R}^n$  is a linear space and  $a \in \mathbb{R}^n$  is a vector, then  $V + a$  is called an *affine space* where  $V + a = \{x + a; x \in V\}$ .

Basic observations

- If  $L \subseteq \mathbb{R}^n$  is an affine space, then  $L + x$  is an affine space for every  $x \in \mathbb{R}^n$ .
- If  $L \subseteq \mathbb{R}^n$  is an affine space, then  $L - x$  is a linear space for every  $x \in L$ . ①
- If  $L \subseteq \mathbb{R}^n$  is an affine space, then  $L - x = L - y$  for every  $x, y \in L$ . ②
- An affine space  $L \subseteq \mathbb{R}^n$  is linear if and only if  $L$  contains the origin  $0$ . ③

System of linear equations

- The set of all solutions of  $Ax = 0$  is a linear space and every linear space is the set of all solutions of  $Ax = 0$  for some  $A$ . ④
- The set of all solutions of  $Ax = b$  is an affine space and every affine space is the set of all solutions of  $Ax = b$  for some  $A$  and  $b$ , assuming  $Ax = b$  is consistent. ⑤

Convex set

Observation (Exercise)

A set  $S \subseteq \mathbb{R}^n$  is an affine space if and only if  $S$  contains whole line given every two points of  $S$ .

Definition

A set  $S \subseteq \mathbb{R}^n$  is *convex* if  $S$  contains whole segment between every two points of  $S$ .

Example

- 1 Use definition and logic.
- 2 Let  $L_i$  be affine space for  $i$  in an index set  $I$  and  $L = \bigcap_{i \in I} L_i$  and  $a \in L$ . We proved that  $L - a = \bigcap_{i \in I} (L_i - a)$  is a linear space which implies that  $L$  is an affine space.
- 3 Use definition and logic.
- 4 Similar as the convex version.
- 5 Similar as the convex version.
- 6 We proved that  $\text{conv}(S)$  is convex, so if  $S = \text{conv}(S)$ , then  $S$  is convex. In order to prove that  $S = \text{conv}(S)$  if  $S$  is convex, we observe that  $\text{conv}(S) \subseteq S$  since  $\text{conv}(S) = \bigcap_{M \supseteq S, M \text{ convex}} M$  and  $S$  is included in this intersection. Similarly,  $\text{conv}(S) \supseteq S$  since every  $M$  in the intersection contains  $S$ .

**Definition**

Let  $\mathbf{v}_1, \dots, \mathbf{v}_k$  be vectors of  $\mathbb{R}^n$  where  $k$  is a positive integer.

- The sum  $\sum_{i=1}^k \alpha_i \mathbf{v}_i$  is called a *linear combination* if  $\alpha_1, \dots, \alpha_k \in \mathbb{R}$ .
- The sum  $\sum_{i=1}^k \alpha_i \mathbf{v}_i$  is called an *affine combination* if  $\alpha_1, \dots, \alpha_k \in \mathbb{R}, \sum_{i=1}^k \alpha_i = 1$ .
- The sum  $\sum_{i=1}^k \alpha_i \mathbf{v}_i$  is called a *convex combination* if  $\alpha_1, \dots, \alpha_k \geq 0$  and  $\sum_{i=1}^k \alpha_i = 1$ .

**Lemma**

Let  $S \subseteq \mathbb{R}^n$  be a non-empty set.

- The set of all linear combinations of  $S$  is a linear space. ①
- The set of all affine combinations of  $S$  is an affine space. ②
- The set of all convex combinations of  $S$  is a convex set. ③

**Lemma**

- A linear space  $S$  contains all linear combinations of  $S$ . ④
- An affine space  $S$  contains all affine combinations of  $S$ . ⑤
- A convex set  $S$  contains all convex combinations of  $S$ . ⑥

that  $\mathbf{y} := \sum_{i=1}^k \frac{\alpha_i}{1-\alpha_k} \mathbf{v}_i$  is a convex combination of  $k-1$  vectors of  $S$  which by induction belongs to  $S$ . Furthermore,  $(1-\alpha_k)\mathbf{y} + \alpha_k \mathbf{v}_k$  is a convex combination of  $S$  which by induction also belongs to  $S$ .

- Similar as the convex version.
- Similar as the convex version.
- Let  $T$  be the set of all convex combinations of  $S$ . First, we prove that  $\text{conv}(S) \subseteq T$ . The definition states that  $\text{conv}(S) = \bigcap_{M \supseteq S, M \text{ convex}} M$  and we proved that  $T$  is a convex set containing  $S$ , so  $T$  is included in this intersection which implies that  $\text{conv}(S)$  is a subset of  $T$ . In order to prove  $\text{conv}(S) \supseteq T$ , we again consider the intersection  $\text{conv}(S) = \bigcap_{M \supseteq S, M \text{ convex}} M$ . We proved that a convex set  $M$  contains all convex combinations of  $M$  which implies that if  $M \supseteq S$  then  $M$  also contains all convex combinations of  $S$ . So, in this intersection every  $M$  contains  $T$  which implies that  $\text{conv}(S) \supseteq T$ .

- If vectors  $\mathbf{v}_1 - \mathbf{v}_0, \dots, \mathbf{v}_k - \mathbf{v}_0$  are linearly dependent, then there exists a non-trivial combination  $\alpha_1, \dots, \alpha_k \in \mathbb{R}$  such that  $\sum_{i=1}^k \alpha_i (\mathbf{v}_i - \mathbf{v}_0) = \mathbf{0}$ . In this case,  $\mathbf{0} = \sum_{i=1}^k \alpha_i (\mathbf{v}_i - \mathbf{v}_0) = \sum_{i=1}^k \alpha_i \mathbf{v}_i - \mathbf{v}_0 \sum_{i=1}^k \alpha_i = \sum_{i=1}^k \alpha_i \mathbf{v}_i$  is a non-trivial affine combination with  $\sum_{i=1}^k \alpha_i = 0$  where  $\alpha_0 = -\sum_{i=1}^k \alpha_i$ . If  $\mathbf{v}_0, \dots, \mathbf{v}_k \in \mathbb{R}^n$  are affinely dependent, then there exists a non-trivial combination  $\alpha_0, \dots, \alpha_k \in \mathbb{R}$  such that  $\sum_{i=0}^k \alpha_i \mathbf{v}_i = \mathbf{0}$  a  $\sum_{i=0}^k \alpha_i = 0$ . In this case,  $\mathbf{0} = \sum_{i=0}^k \alpha_i \mathbf{v}_i = \alpha_0 \mathbf{v}_0 + \sum_{i=1}^k \alpha_i \mathbf{v}_i = \sum_{i=1}^k \alpha_i (\mathbf{v}_i - \mathbf{v}_0)$  is a non-trivial linear combination of vectors  $\mathbf{v}_1 - \mathbf{v}_0, \dots, \mathbf{v}_k - \mathbf{v}_0$ .
- Use the previous observation with  $\mathbf{v}_0 = \mathbf{0}$ .

- We have to verify that the set of all linear combinations has closure under addition and multiplication by scalars. In order to verify the closure under multiplication, let  $\sum_{i=1}^k \alpha_i \mathbf{v}_i$  be a linear combination of  $S$  and  $c \in \mathbb{R}$  be a scalar. Then,  $c \sum_{i=1}^k \alpha_i \mathbf{v}_i = \sum_{i=1}^k (c\alpha_i) \mathbf{v}_i$  is a linear combination of  $S$ . Similarly, the set of all linear combinations has closure under addition and it contains the origin.
- Similar as the convex version: Show that  $S$  contains whole line defined by arbitrary pair of points of  $S$ .
- Let  $\sum_{i=1}^k \alpha_i \mathbf{u}_i$  and  $\sum_{j=1}^l \beta_j \mathbf{v}_j$  be two convex combinations of  $S$ . In order to prove that the set of all convex combinations of  $S$  contains the line segment between  $\sum_{i=1}^k \alpha_i \mathbf{u}_i$  and  $\sum_{j=1}^l \beta_j \mathbf{v}_j$ , let us consider  $\gamma_1, \gamma_2 \geq 0$  such that  $\gamma_1 + \gamma_2 = 1$ . Then,  $\gamma_1 \sum_{i=1}^k \alpha_i \mathbf{u}_i + \gamma_2 \sum_{j=1}^l \beta_j \mathbf{v}_j = \sum_{i=1}^k (\gamma_1 \alpha_i) \mathbf{u}_i + \sum_{j=1}^l (\gamma_2 \beta_j) \mathbf{v}_j$  is a convex combination of  $S$  since  $(\gamma_1 \alpha_i), (\gamma_2 \beta_j) \geq 0$  and  $\sum_{i=1}^k (\gamma_1 \alpha_i) + \sum_{j=1}^l (\gamma_2 \beta_j) = 1$ .
- Similar as the convex version.
- Let  $\sum_{i=1}^k \alpha_i \mathbf{v}_i$  be an affine combination of  $S$ . Since  $S - \mathbf{v}_k$  is a linear space, the linear combination  $\sum_{i=1}^k \alpha_i (\mathbf{v}_i - \mathbf{v}_k)$  of  $S - \mathbf{v}_k$  belongs into  $S - \mathbf{v}_k$ . Hence,  $\mathbf{v}_k + \sum_{i=1}^k \alpha_i (\mathbf{v}_i - \mathbf{v}_k) = \sum_{i=1}^k \alpha_i \mathbf{v}_i$  belongs to  $S$ .
- We prove by induction on  $k$  that  $S$  contains every convex combination  $\sum_{i=1}^k \alpha_i \mathbf{v}_i$  of  $S$ . The statement holds for  $k \leq 2$  by the definition of a convex set. Let  $\sum_{i=1}^k \alpha_i \mathbf{v}_i$  be a convex combination of  $k$  vectors of  $S$  and we assume that  $\alpha_k < 1$ , otherwise  $\alpha_1 = \dots = \alpha_{k-1} = 0$  so  $\sum_{i=1}^k \alpha_i \mathbf{v}_i = \mathbf{v}_k \in S$ . Hence,  $\alpha_1 = \dots = \alpha_{k-1} = 0$  so  $\sum_{i=1}^k \alpha_i \mathbf{v}_i = \mathbf{v}_k \in S$ . Hence,  $\sum_{i=1}^k \alpha_i \mathbf{v}_i = (1 - \alpha_k) \sum_{i=1}^{k-1} \frac{\alpha_i}{1-\alpha_k} \mathbf{v}_i + \alpha_k \mathbf{v}_k = (1 - \alpha_k) \mathbf{y} + \alpha_k \mathbf{v}_k$  where we observe

**Theorem**

Let  $S \subseteq \mathbb{R}^n$  be a non-empty set.

- The linear hull of a set  $S$  is the set of all linear combinations of  $S$ . ①
- The affine hull of a set  $S$  is the set of all affine combinations of  $S$ . ②
- The convex hull of a set  $S$  is the set of all convex combinations of  $S$ . ③

Independence and base

**Definition**

- A set of vectors  $S \subseteq \mathbb{R}^n$  is *linearly independent* if no vector of  $S$  is a linear combination of other vectors of  $S$ .
- A set of vectors  $S \subseteq \mathbb{R}^n$  is *affinely independent* if no vector of  $S$  is an affine combination of other vectors of  $S$ .

**Observation (Exercise)**

- Vectors  $\mathbf{v}_1, \dots, \mathbf{v}_k \in \mathbb{R}^n$  are linearly dependent if and only if there exists a non-trivial combination  $\alpha_1, \dots, \alpha_k \in \mathbb{R}$  such that  $\sum_{i=1}^k \alpha_i \mathbf{v}_i = \mathbf{0}$ .
- Vectors  $\mathbf{v}_1, \dots, \mathbf{v}_k \in \mathbb{R}^n$  are affinely dependent if and only if there exists a non-trivial combination  $\alpha_1, \dots, \alpha_k \in \mathbb{R}$  such that  $\sum_{i=1}^k \alpha_i \mathbf{v}_i = \mathbf{0}$  a  $\sum_{i=1}^k \alpha_i = 0$ .

**Observation**

- Vectors  $\mathbf{v}_0, \dots, \mathbf{v}_k \in \mathbb{R}^n$  are affinely independent if and only if vectors  $\mathbf{v}_1 - \mathbf{v}_0, \dots, \mathbf{v}_k - \mathbf{v}_0$  are linearly independent. ①
- Vectors  $\mathbf{v}_1, \dots, \mathbf{v}_k \in \mathbb{R}^n$  are linearly independent if and only if vectors  $\mathbf{0}, \mathbf{v}_1, \dots, \mathbf{v}_k$  are affinely independent. ②

Basis

**Definition**

Let  $B \subseteq \mathbb{R}^n$  and  $S \subseteq \mathbb{R}^n$ .

- $B$  is a *base* of a linear space  $S$  if  $B$  are linearly independent and  $\text{span}(B) = S$ .
- $B$  is a *base* of an affine space  $S$  if  $B$  are affinely independent and  $\text{aff}(B) = S$ .

**Observation**

- All linear bases of a linear space have the same cardinality.
- All affine bases of an affine space have the same cardinality. ①

**Observation**

Let  $S$  be a linear space and  $B \subseteq S \setminus \{\mathbf{0}\}$ . Then,  $B$  is a linear base of  $S$  if and only if  $B \cup \{\mathbf{0}\}$  is an affine base of  $S$ .

**Definition**

- The *dimension* of a linear space is the cardinality of its linear base.
- The *dimension* of an affine space is the cardinality of its affine base minus one.
- The *dimension*  $\dim(S)$  of a set  $S \subseteq \mathbb{R}^n$  is the dimension of affine hull of  $S$ .

- For the sake of contradiction, let  $\mathbf{a}_1, \dots, \mathbf{a}_k$  and  $\mathbf{b}_1, \dots, \mathbf{b}_l$  be two basis of an affine space  $L = V + \mathbf{x}$  where  $V$  a linear space and  $l > k$ . Then,  $\mathbf{a}_1 - \mathbf{x}, \dots, \mathbf{a}_k - \mathbf{x}$  and  $\mathbf{b}_1 - \mathbf{x}, \dots, \mathbf{b}_l - \mathbf{x}$  are two linearly independent sets of vectors of  $V$ . Hence, there exists  $i$  such that  $\mathbf{a}_1 - \mathbf{x}, \dots, \mathbf{a}_k - \mathbf{x}, \mathbf{b}_i - \mathbf{x}$  are linearly independent, so  $\mathbf{a}_1, \dots, \mathbf{a}_k, \mathbf{b}_i$  are affinely independent. Therefore,  $\mathbf{b}_i$  cannot be obtained by an affine combination of  $\mathbf{a}_1, \dots, \mathbf{a}_k$  and  $\mathbf{b}_j \notin \text{aff}(\mathbf{a}_1, \dots, \mathbf{a}_k)$  which contradicts the assumption that  $\mathbf{a}_1, \dots, \mathbf{a}_k$  is a basis of  $L$ .

- Let  $\mathbf{x} \in \text{conv}(S)$ . Let  $\mathbf{x} = \sum_{i=1}^k \alpha_i \mathbf{x}_i$  be a convex combination of points of  $S$  with the smallest  $k$ . If  $\mathbf{x}_1, \dots, \mathbf{x}_k$  are affinely dependent, then there exists a combination  $\mathbf{0} = \sum \beta_i \mathbf{x}_i$  such that  $\sum \beta_i = 0$  and  $\beta \neq \mathbf{0}$ . Since this combination is non-trivial, there exists  $j$  such that  $\beta_j > 0$  and  $\frac{\alpha_j}{\beta_j}$  is minimal. Let  $\gamma_i = \alpha_i - \frac{\alpha_j \beta_i}{\beta_j}$ . Observe that
  - $\mathbf{x} = \sum_{i \neq j} \gamma_i \mathbf{x}_i$
  - $\sum_{i \neq j} \gamma_i = 1$
  - $\gamma_i \geq 0$  for all  $i \neq j$
 which contradicts the minimality of  $k$ .

## Carathéodory

**Theorem (Carathéodory)**  
 Let  $S \subseteq \mathbb{R}^n$ . Every point of  $\text{conv}(S)$  is a convex combinations of affinely independent points of  $S$ . ①

**Corollary**  
 Let  $S \subseteq \mathbb{R}^n$  be a set of dimension  $d$ . Then, every point of  $\text{conv}(S)$  is a convex combinations of at most  $d + 1$  points of  $S$ .

## System of linear equations and inequalities

**Definition**

- A *hyperplane* is a set  $\{\mathbf{x} \in \mathbb{R}^n; \mathbf{a}^T \mathbf{x} = b\}$  where  $\mathbf{a} \in \mathbb{R}^n \setminus \{\mathbf{0}\}$  and  $b \in \mathbb{R}$ .
- A *half-space* is a set  $\{\mathbf{x} \in \mathbb{R}^n; \mathbf{a}^T \mathbf{x} \leq b\}$  where  $\mathbf{a} \in \mathbb{R}^n \setminus \{\mathbf{0}\}$  and  $b \in \mathbb{R}$ .
- A *polyhedron* is an intersection of finitely many half-spaces.
- A *polytope* is a bounded polyhedron.

**Observation**  
 For every  $\mathbf{a} \in \mathbb{R}^n$  and  $b \in \mathbb{R}$ , the set of all  $\mathbf{x} \in \mathbb{R}^n$  satisfying  $\mathbf{a}^T \mathbf{x} \leq b$  is convex.

**Corollary**  
 Every polyhedron  $\{\mathbf{x}; \mathbf{A}\mathbf{x} \leq \mathbf{b}\}$  is convex.

## Hyperplane separation theorem

**Theorem (strict version)**  
 Let  $C, D \subseteq \mathbb{R}^n$  be non-empty, closed, convex and disjoint sets and  $C$  be bounded. Then, there exists a hyperplane  $\mathbf{a}^T \mathbf{x} = b$  which strictly separates  $C$  and  $D$ ; that is  $C \subseteq \{\mathbf{x}; \mathbf{a}^T \mathbf{x} < b\}$  and  $D \subseteq \{\mathbf{x}; \mathbf{a}^T \mathbf{x} > b\}$ .

## Mathematical analysis

**Definition**

- A set  $S \subseteq \mathbb{R}^n$  is *closed* if  $S$  contains the limit of every converging sequence of points of  $S$ .
- A set  $S \subseteq \mathbb{R}^n$  is *bounded* if there exists  $b \in \mathbb{R}$  s.t. for every  $\mathbf{x} \in S$  holds  $\|\mathbf{x}\| < b$ .
- A set  $S \subseteq \mathbb{R}^n$  is *compact* if every sequence of points of  $S$  contains a converging subsequence with limit in  $S$ .

**Theorem**  
 A set  $S \subseteq \mathbb{R}^n$  is compact if and only if  $S$  is closed and bounded.

**Theorem**  
 If  $f : S \rightarrow \mathbb{R}$  is a continuous function on a compact set  $S \subseteq \mathbb{R}^n$ , then  $S$  contains a point  $\mathbf{x}$  maximizing  $f$  over  $S$ ; that is,  $f(\mathbf{x}) \geq f(\mathbf{y})$  for every  $\mathbf{y} \in S$ .

**Definition**

- Infimum of a set  $S \subseteq \mathbb{R}$  is  $\inf(S) = \max\{b \in \mathbb{R}; b \leq x \forall x \in S\}$ .
- Supremum of a set  $S \subseteq \mathbb{R}$  is  $\sup(S) = \min\{b \in \mathbb{R}; b \geq x \forall x \in S\}$ .
- $\inf(\emptyset) = \infty$  and  $\sup(\emptyset) = -\infty$
- $\inf(S) = -\infty$  if  $S$  has no lower bound

## Hyperplane separation theorem

**Theorem (strict version)**  
 Let  $C, D \subseteq \mathbb{R}^n$  be non-empty, closed, convex and disjoint sets and  $C$  be bounded. Then, there exists a hyperplane  $\mathbf{a}^T \mathbf{x} = b$  which strictly separates  $C$  and  $D$ ; that is  $C \subseteq \{\mathbf{x}; \mathbf{a}^T \mathbf{x} < b\}$  and  $D \subseteq \{\mathbf{x}; \mathbf{a}^T \mathbf{x} > b\}$ .

**Proof (overview)**

- Find  $\mathbf{c} \in C$  and  $\mathbf{d} \in D$  with minimal distance  $\|\mathbf{d} - \mathbf{c}\|$ .
  - Let  $m = \inf\{\|\mathbf{d} - \mathbf{c}\|; \mathbf{c} \in C, \mathbf{d} \in D\}$ .
  - For every  $n \in \mathbb{N}$  there exists  $\mathbf{c}_n \in C$  and  $\mathbf{d}_n \in D$  such that  $\|\mathbf{d}_n - \mathbf{c}_n\| \leq m + \frac{1}{n}$ .
  - Since  $C$  is compact, there exists a subsequence  $\{\mathbf{c}_{n_i}\}_{i=1}^{\infty}$  converging to  $\mathbf{c} \in C$ .
  - There exists  $\mathbf{z} \in \mathbb{R}^n$  such that for every  $n \in \mathbb{N}$  the distance  $\|\mathbf{d}_n - \mathbf{c}\|$  is at most  $z$ .
  - Since the set  $D \cap \{\mathbf{x} \in \mathbb{R}^n; \|\mathbf{x} - \mathbf{c}\| \leq z\}$  is compact, the sequence  $\{\mathbf{d}_{n_i}\}_{i=1}^{\infty}$  has a subsequence  $\{\mathbf{d}_{n_{i_j}}\}_{j=1}^{\infty}$  converging to  $\mathbf{d} \in D$ .
  - Observe that the distance  $\|\mathbf{d} - \mathbf{c}\|$  is  $m$ .
- The required hyperplane is  $\mathbf{a}^T \mathbf{x} = b$  where  $\mathbf{a} = \mathbf{d} - \mathbf{c}$  and  $b = \frac{\mathbf{a}^T \mathbf{c} + \mathbf{a}^T \mathbf{d}}{2}$ .
  - We prove that  $\mathbf{a}^T \mathbf{c}' \leq \mathbf{a}^T \mathbf{c} < b < \mathbf{a}^T \mathbf{d} \leq \mathbf{a}^T \mathbf{d}'$  for every  $\mathbf{c}' \in C$  and  $\mathbf{d}' \in D$ .
  - Since  $C$  is convex,  $\mathbf{y} = \mathbf{c} + \alpha(\mathbf{c}' - \mathbf{c}) \in C$  for every  $0 \leq \alpha \leq 1$ .
  - From the minimality of the distance  $\|\mathbf{d} - \mathbf{c}\|$  it follows that  $\|\mathbf{d} - \mathbf{y}\|^2 \geq \|\mathbf{d} - \mathbf{c}\|^2$ .
  - Using elementary operations observe that  $\frac{\alpha}{2} \|\mathbf{c}' - \mathbf{c}\|^2 + \mathbf{a}^T \mathbf{c} \geq \mathbf{a}^T \mathbf{c}'$ .
  - which holds for arbitrarily small  $\alpha > 0$ , it follows that  $\mathbf{a}^T \mathbf{c} \geq \mathbf{a}^T \mathbf{c}'$  holds.

- 1  $\|\mathbf{d}_n - \mathbf{c}\| \leq \|\mathbf{d}_n - \mathbf{c}_n\| + \|\mathbf{c}_n - \mathbf{c}\| \leq m + 1 + \max\{\|\mathbf{c}' - \mathbf{c}''\|\}; \mathbf{c}', \mathbf{c}'' \in C\} = z$
- 2  $\|\mathbf{d} - \mathbf{c}\| \leq \|\mathbf{d} - \mathbf{d}_n\| + \|\mathbf{d}_n - \mathbf{c}_n\| + \|\mathbf{c}_n - \mathbf{c}\| \rightarrow m$
- 3 The inner two inequalities are obvious. We only prove the first inequality since the last one is analogous.
- 4

$$\begin{aligned} \|\mathbf{d} - \mathbf{y}\|^2 &\geq \|\mathbf{d} - \mathbf{c}\|^2 \\ (\mathbf{d} - \mathbf{c} - \alpha(\mathbf{c}' - \mathbf{c}))^\top (\mathbf{d} - \mathbf{c} - \alpha(\mathbf{c}' - \mathbf{c})) &\geq (\mathbf{d} - \mathbf{c})^\top (\mathbf{d} - \mathbf{c}) \\ \alpha^2 (\mathbf{c}' - \mathbf{c})^\top (\mathbf{c}' - \mathbf{c}) - 2\alpha (\mathbf{d} - \mathbf{c})^\top (\mathbf{c}' - \mathbf{c}) &\geq 0 \\ \frac{\alpha}{2} \|\mathbf{c}' - \mathbf{c}\|^2 + \mathbf{a}^\top \mathbf{c} &\geq \mathbf{a}^\top \mathbf{c}' \end{aligned}$$

- 1 Observe, that every face of a polyhedron is also a polyhedron.

- 1 There exists  $x \in P \setminus P'$ . Since  $\text{aff}(P') \subseteq \{x; A'_{i,*}x = b'_i\}$ , it follows that  $x \notin \text{aff}(P')$ . Hence,  $\dim(P') + 1 = \dim(P' \cup \{x\}) \leq \dim(P)$ .

## A bijection between faces and inequalities

### Theorem

Let  $P = \{x \in \mathbb{R}^n; A'x = b', A''x \leq b''\}$  be a minimal defining system of a polyhedron  $P$ . Then, there exists a bijection between facets of  $P$  and inequalities  $A''x \leq b''$ .

### Proof

- 1 Let  $R_i = \{x; A''_{i,*}x = b''_i\}$  and  $F_i = P \cap R_i$ .
- 2 From minimality it follows that  $R_i$  is a supporting hyperplane, and therefore,  $F_i$  is a face.
- 3 There exists a point  $y^i \in F_i$  satisfying  $A''_{j,*}y^i < b''_j$  for all  $j \neq i$ . ①
- 4 So  $\dim(F_i) = \dim(P) - 1$  and  $F_i$  is a facet.
- 5 Furthermore,  $y^j \notin F_i$  for all  $j \neq i$ , so  $F_i \neq F_j$  for  $j \neq i$ .
- 6 For contradiction, let  $F$  be another facet.
- 7 There exists a facet  $i$  such  $F \subseteq F_i$ . ②
- 8  $F$  is a proper face of  $F_i$  and so its dimension is at most  $\dim(P) - 2$  contradicting the assumption that  $F$  is a proper facet.

## Faces of a polyhedron

### Definition

Let  $P$  be a polyhedron. A half-space  $\alpha^\top x \leq \beta$  is called a *supporting hyperplane* of  $P$  if the inequality  $\alpha^\top x \leq \beta$  holds for every  $x \in P$  and the hyperplane  $\alpha^\top x = \beta$  has a non-empty intersection with  $P$ .

The set of point in the intersection  $P \cap \{x; \alpha^\top x = \beta\}$  is called a *face* of  $P$ . By convention, the empty set and  $P$  are also faces, and the other faces are *proper faces*. ①

### Definition

Let  $P$  be a  $d$ -dimensional polyhedron.

- A 0-dimensional face of  $P$  is called a *vertex* of  $P$ .
- A 1-dimensional face of  $P$  is called an *edge* of  $P$ .
- A  $(d - 1)$ -dimensional face of  $P$  is called a *facet* of  $P$ .

## Minimal defining system of a polyhedron

### Definition

$P = \{x \in \mathbb{R}^n; A'x = b', A''x \leq b''\}$  is a *minimal defining system* of a polyhedron  $P$  if

- no condition can be removed and
- no inequality can be replaced by equality

without changing the polyhedron  $P$ .

### Observation

Every polyhedron has a minimal defining system.

### Lemma

Let  $P = \{x \in \mathbb{R}^n; A'x = b', A''x \leq b''\}$  be a *minimal defining system* of a polyhedron  $P$ . Let  $P' = \{x \in P; A''_{i,*}x = b''_i\}$  for some row  $i$  of  $A''x \leq b''$ . Then  $\dim(P') < \dim(P)$ . ①

### Corollary

Let  $P = \{x; Ax \leq b\}$  of dimension  $d$ . Then for every row  $i$ , either

- $P \cap \{x; A_{i,*}x = b_i\} = P$  or
- $P \cap \{x; A_{i,*}x = b_i\} = \emptyset$  or
- $P \cap \{x; A_{i,*}x = b_i\}$  is a proper face of dimension at most  $d - 1$ .

## A point inside a polyhedron

### Theorem

Let  $P$  be a non-empty polyhedron defined by a minimal system  $\{x \in \mathbb{R}^n; A'x = b', A''x \leq b''\}$ . Then,

- 1 there exists a point  $z \in P$  such that  $A''z < b''$  and
- 2  $\dim(P) = n - \text{rank}(A')$ , and
- 3 and  $z$  does not belong in any proper face of  $P$ .

### Proof

- 1 There exists a point  $z \in P$  such that  $A''z < b''$ .
  - 1 For every row  $i$  of  $A''x \leq b''$  there exists  $z^i \in P$  such that  $A''_{i,*}z^i < b''_i$ .
  - 2 Let  $z = \frac{1}{m'} \sum_{i=1}^{m'} z^i$  be the center of gravity.
  - 3 Since  $z$  is a convex combination of points of  $P$ , point  $z$  belongs to  $P$  and  $A''z < b''$ .
- 2  $\dim(P) = n - \text{rank}(A')$ 
  - 1 Let  $L$  be the affine space defined by  $A'x = b'$ .
  - 2 There exists  $\epsilon > 0$  such that  $P$  contains whole ball  $B = \{x \in L; \|x - z\| \leq \epsilon\}$ .
  - 3 Vectors of a base of the linear space  $L - z$  can be scaled so that they belong into  $B - z$ .
  - 4  $\dim(L) \geq \dim(P) \geq \dim(B) \geq \dim(L) = n - \text{rank}(A')$ .
- 3 The point  $z$  does not belong in any proper face of  $P$ .
  - 1 The point  $z$  cannot belong into any proper face of  $P$  because a supporting hyperplane of such a face split the ball  $B$ .

- 1 From minimality it follows that there exists  $x$  satisfying all conditions of  $P$  except  $A''_{i,*}x < b''_i$ . Let  $z$  be a point from the previous theorem. A point  $y^i$  can be obtained as a convex combination of  $x$  and  $z$ .
- 2 Otherwise  $\frac{1}{m'} \sum_{i=1}^{m'} y^i$  satisfies strictly all condition contradicting the assumption that  $F$  is a proper facet.

## Definition

A polyhedron  $P \subseteq \mathbb{R}^n$  is of full-dimension if  $\dim(P) = n$ .

## Corollary

If  $P$  is a full-dimensional polyhedron, then  $P$  has exactly one minimal defining system up-to multiplying conditions by constants.  $\odot$

## Minkowski-Weyl

## Theorem (Minkowski-Weyl)

A set  $S \subseteq \mathbb{R}^n$  is a polytope if and only if there exists a finite set  $V \subseteq \mathbb{R}^n$  such that  $S = \text{conv}(V)$ .

## Illustration

## Minkowski-Weyl

## Theorem (Minkowski-Weyl)

A set  $S \subseteq \mathbb{R}^n$  is a polytope if and only if there exists a finite set  $V \subseteq \mathbb{R}^n$  such that  $S = \text{conv}(V)$ .

## Lemma

A condition  $\alpha^T \mathbf{v} \leq \beta$  is satisfied by all points  $\mathbf{v} \in V$  if and only if the condition is satisfied by all points  $\mathbf{v} \in \text{conv}(V)$ .

Proof of the implication  $\Leftarrow$  (main steps)

- 1 Let  $Q = \left\{ \begin{pmatrix} \alpha \\ \beta \end{pmatrix}; \alpha \in \mathbb{R}^n, \beta \in \mathbb{R}, -1 \leq \alpha \leq 1, -1 \leq \beta \leq 1, \alpha^T \mathbf{v} \leq \beta \forall \mathbf{v} \in V \right\}$ .  $\odot$
- 2 Since  $Q$  is a polytope, there exists a finite set  $W \subseteq \mathbb{R}^{n+1}$  s.t.  $Q = \text{conv}(W)$ .  $\odot$
- 3 Let  $Y = \left\{ \mathbf{x} \in \mathbb{R}^n; \alpha^T \mathbf{x} \leq \beta \forall \begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in W \right\}$  and we prove that  $\text{conv}(V) = Y$ .
  - $\subseteq$  From  $V \subseteq Y$  it follows that  $\text{conv}(V) \subseteq Y$ .  $\odot$
  - $\supseteq$  We prove that  $\mathbf{x} \notin \text{conv}(V) \Rightarrow \mathbf{x} \notin Y$ .
    - There exists  $\alpha \in \mathbb{R}^n, \beta \in \mathbb{R}$  s.t.  $\alpha^T \mathbf{x} > \beta$  and  $\forall \mathbf{v} \in V: \alpha^T \mathbf{v} \leq \beta$ .  $\odot$
    - Assume that  $-1 \leq \alpha \leq 1, -1 \leq \beta \leq 1$ .  $\odot$
    - Observe that  $\begin{pmatrix} \alpha \\ \beta \end{pmatrix} \in Q$  and  $\mathbf{x}$  fails at least one condition of  $Q$ .
    - Hence,  $\mathbf{x}$  fails at least one condition of  $W$ .  $\odot$

## Faces

## Theorem

Let  $P$  be a polyhedron and  $V$  its vertices. Then,  $\mathbf{x}$  is a vertex of  $P$  if and only if  $\mathbf{x} \notin \text{conv}(P \setminus \{\mathbf{x}\})$ . Furthermore, if  $P$  is bounded, then  $P = \text{conv}(V)$ .

## Proof (only for bounded polyhedrons)

- Let  $V_0$  be (inclusion) minimal set such that  $P = \text{conv}(V_0)$ .
- Let  $V_0 = \{\mathbf{x} \in P; \mathbf{x} \notin \text{conv}(P \setminus \{\mathbf{x}\})\}$ .
- We prove that  $V = V_0$ .  $\odot$

## Minkowski-Weyl

## Theorem (Minkowski-Weyl)

A set  $S \subseteq \mathbb{R}^n$  is a polytope if and only if there exists a finite set  $V \subseteq \mathbb{R}^n$  such that  $S = \text{conv}(V)$ .

Proof of the implication  $\Rightarrow$  (main steps) by induction on  $\dim(S)$ 

For  $\dim(S) = 0$  the size of  $S$  is 1 and the statement holds. Assume that  $\dim(S) > 0$ .

- 1 Let  $S = \{\mathbf{x} \in \mathbb{R}^n; A' \mathbf{x} = \mathbf{b}', A'' \mathbf{x} \leq \mathbf{b}''\}$  be a minimal defining system.
- 2 Let  $S_i = \{\mathbf{x} \in S; A'_i \mathbf{x} = \mathbf{b}'_i\}$  where  $i$  is a row of  $A'' \mathbf{x} \leq \mathbf{b}''$ .
- 3 Since  $\dim(S_i) < \dim(S)$ , there exists a finite set  $V_i \subseteq \mathbb{R}^n$  such that  $S_i = \text{conv}(V_i)$ .
- 4 Let  $V = \bigcup_i V_i$ . We prove that  $\text{conv}(V) = S$ .
  - $\subseteq$  Follows from  $V_i \subseteq S_i \subseteq S$  and convexity of  $S$ .
  - $\supseteq$  Let  $\mathbf{x} \in S$ . Let  $L$  be a line containing  $\mathbf{x}$ .  
 $S \cap L$  is a line segment with end-vertices  $\mathbf{u}$  and  $\mathbf{v}$ .  
 There exists  $i, j \in I$  such that  $A'_i \mathbf{u} = \mathbf{b}'_i$  and  $A'_j \mathbf{v} = \mathbf{b}'_j$ .  
 Since  $\mathbf{u} \in S_i$  and  $\mathbf{v} \in S_j$ , points  $\mathbf{u}$  and  $\mathbf{v}$  are convex combinations of  $V_i$  and  $V_j$ , resp.  
 Since  $\mathbf{x}$  is also a convex combination of  $\mathbf{u}$  and  $\mathbf{v}$ , we have  $\mathbf{x} \in \text{conv}(V)$ .

- 1 Observe that  $\alpha^T \mathbf{v} \leq \beta$  means the same as  $\begin{pmatrix} \alpha \\ -1 \end{pmatrix}^T \begin{pmatrix} \mathbf{v} \\ \beta \end{pmatrix} \leq 0$ . Therefore,  $Q$  is described by  $|V| + 2n + 2$  inequalities. Furthermore, conditions  $-1 \leq \alpha \leq 1$  and  $-1 \leq \beta \leq 1$  implies that  $Q$  is bounded.
- 2 Here we use the implication  $\Rightarrow$  of Minkowski-Weyl theorem which we already proved.
- 3 Every point of  $V$  satisfies all conditions of  $Q$  since  $Q$  contains only conditions satisfied by all points of  $V$ . Since  $W \subseteq \text{conv}(W) = Q$ , it follows that every point of  $V$  satisfies all conditions of  $W$ . Hence,  $V \subseteq Y$ . Since  $Y$  is convex, the inclusion  $\text{conv}(V) \subseteq Y$ .
- 4 Apply Hyperplane separation theorem on sets  $Q$  and  $\{\mathbf{x}\}$ .
- 5 Scale the vector  $\begin{pmatrix} \alpha \\ \beta \end{pmatrix}$  so that it fit into this box.
- 6 Use lemma.

- 1  $\subseteq V_0$ : Let  $\mathbf{z} \in V$  be a vertex. By definition, there exists a supporting hyperplane  $\mathbf{c}^T \mathbf{x} = t$  such that  $P \cap \{\mathbf{x}; \mathbf{c}^T \mathbf{x} = t\} = \{\mathbf{z}\}$ . Since  $\mathbf{c}^T \mathbf{x} < t$  for all  $\mathbf{x} \in P \setminus \{\mathbf{z}\}$ , it follows that  $\mathbf{z} \in V_0$ .
- 2  $V_0 \subseteq V_0$ : Let  $\mathbf{z} \in V_0$ . Since  $\text{conv}(P \setminus \{\mathbf{z}\}) \neq P$ , it follows that  $\mathbf{z} \in V_0$ .
- 3  $V_0 \subseteq V$ : Let  $\mathbf{z} \in V_0$  and  $D = \text{conv}(V_0 \setminus \{\mathbf{z}\})$ . From Minkowski-Weyl's theorem it follows that  $V_0$  is finite and therefore,  $D$  is compact. By the separation theorem, there exists a hyperplane  $\mathbf{c}^T \mathbf{x} = r$  separating  $\{\mathbf{z}\}$  and  $D$ , that is  $\mathbf{c}^T \mathbf{x} < r < \mathbf{c}^T \mathbf{z}$  for all  $\mathbf{x} \in D$ . Let  $t = \mathbf{c}^T \mathbf{z}$ . Hence,  $A = \{\mathbf{x}; \mathbf{c}^T \mathbf{x} = t\}$  is a supporting hyperplane of  $P$ . We prove that  $A \cap P = \{\mathbf{z}\}$ . For contradiction, let  $\mathbf{z}' \in P \cap A$  be a different from  $\mathbf{z}$ . Then, there exists a convex combination  $\mathbf{z}' = \alpha_1 \mathbf{x}_1 + \dots + \alpha_k \mathbf{x}_k + \alpha_0 \mathbf{z}$  of  $V_0$ . From  $\mathbf{z} \neq \mathbf{z}'$  it follows that  $\alpha_0 < 1$  and  $\alpha_i > 0$  for some  $i$ . Since  $\alpha_0 \mathbf{c}^T \mathbf{z} = t$  and  $\alpha_i \mathbf{c}^T \mathbf{x}_i < t$  and  $\alpha_i \mathbf{c}^T \mathbf{x}_i \leq t$ , it holds that  $\mathbf{c}^T \mathbf{z}' < t$  which contradicts the assumption that  $\mathbf{z}' \in A$ .

Theorem (A face of a face is a face)

Let  $F$  be a face of a polyhedron  $P$  and let  $E \subseteq F$ . Then,  $E$  is a face of  $F$  if and only if  $E$  is a face of  $P$ .

Observation (Exercise)

The intersection of two faces of a polyhedron  $P$  is a face of  $P$ .

Observation (Exercise)

A non-empty set  $F \subseteq \mathbb{R}^n$  is a face of a polyhedron  $P = \{x \in \mathbb{R}^n; Ax \leq b\}$  if and only if  $F$  is the set of all optimal solutions of a linear programming problem  $\min \{c^T x; Ax \leq b\}$  for some vector  $c \in \mathbb{R}^n$ .

Notation

Notation used in the Simplex method

- Linear programming problem in the equation form is a problem to find  $x \in \mathbb{R}^n$  which maximizes  $c^T x$  and satisfies  $Ax = b$  and  $x \geq 0$  where  $A \in \mathbb{R}^{m \times n}$  and  $b \in \mathbb{R}^m$ .
- We assume that rows of  $A$  are linearly independent.
- For a subset  $B \subseteq \{1, \dots, n\}$ , let  $A_B$  be the matrix consisting of columns of  $A$  whose indices belong to  $B$ .
- Similarly for vectors,  $x_B$  denotes the coordinates of  $x$  whose indices belong to  $B$ .
- The set  $N = \{1, \dots, n\} \setminus B$  denotes the remaining columns.

Example

Consider  $B = \{2, 4\}$ . Then,  $N = \{1, 3, 5\}$  and

$$A = \begin{pmatrix} 1 & 3 & 5 & 6 & 0 \\ 2 & 4 & 8 & 9 & 7 \end{pmatrix} \quad A_B = \begin{pmatrix} 3 & 6 \\ 4 & 9 \end{pmatrix} \quad A_N = \begin{pmatrix} 1 & 5 & 0 \\ 2 & 8 & 7 \end{pmatrix}$$

$$x^T = (3, 4, 6, 2, 7) \quad x_B^T = (4, 2) \quad x_N^T = (3, 6, 7)$$

Note that  $Ax = A_B x_B + A_N x_N$ .

- Remember that non-basic variables are always equal to zero.
- If  $x$  is a basic feasible solution and  $B$  is the corresponding basis, then  $x_N = 0$  and so  $K \subseteq B$  which implies that columns of  $A_K$  are also linearly independent. If columns of  $A_K$  are linearly independent, then we can extend  $K$  into  $B$  by adding columns of  $A$  so that columns of  $A_B$  are linearly independent which implies that  $B$  is a basis of  $x$ .
- Note that basic variables can also be zero. In this case, the basis  $B$  corresponding to a basic solution  $x$  may not be unique since there may be many ways to extend  $K$  into a basis  $B$ . This is called degeneracy.

Example: Initial simplex tableau

Simplex tableau

$$\begin{array}{rcl} x_3 & = & 1 + x_1 - x_2 \\ x_4 & = & 3 - x_1 \\ x_5 & = & 2 - x_2 \\ \hline z & = & x_1 + x_2 \end{array}$$

Initial basic feasible solution

- $B = \{3, 4, 5\}$ ,  $N = \{1, 2\}$
- $x = (0, 0, 1, 3, 2)$

Pivot

Two edges from the vertex  $(0, 0, 1, 3, 2)$ :

- $(t, 0, 1 + t, 3 - t, 2)$  when  $x_1$  is increased by  $t$
- $(0, r, 1 - r, 3, 2 - r)$  when  $x_2$  is increased by  $r$

These edges give feasible solutions for:

- $t \leq 3$  since  $x_3 = 1 + t \geq 0$  and  $x_4 = 3 - t \geq 0$  and  $x_5 = 2 \geq 0$
- $r \leq 1$  since  $x_3 = 1 - r \geq 0$  and  $x_4 = 3 \geq 0$  and  $x_5 = 2 - r \geq 0$

In both cases, the objective function is increasing. We choose  $x_2$  as a pivot.

- Duality of linear programming
- Ellipsoid method
- Matching

Basic feasible solutions

Definitions

Consider the equation form  $Ax = b$  and  $x \geq 0$  with  $n$  variables and  $\text{rank}(A) = m$  rows.

- A set of columns  $B$  is a *basis* if  $A_B$  is a regular matrix.
- The *basic solution*  $x$  corresponding to a basis  $B$  is  $x_N = 0$  and  $x_B = A_B^{-1} b$ .
- A basic solution satisfying  $x \geq 0$  is called *basic feasible solution*.
- $x_B$  are called basic variables and  $x_N$  are called non-basic variables. ①

Lemma

A feasible solution  $x$  is basic if and only if the columns of the matrix  $A_K$  are linearly independent where  $K = \{j \in \{1, \dots, n\}; x_j > 0\}$ .

Observation

Basic feasible solutions are exactly vertices of the polyhedron  $P = \{x; Ax = b, x \geq 0\}$ . ② ③

Example: Initial simplex tableau

Canonical form

$$\begin{array}{rcl} \text{Maximize} & x_1 & + x_2 \\ & -x_1 & + x_2 \leq 1 \\ & x_1 & \leq 3 \\ & & x_2 \leq 2 \\ & & x_1, x_2 \geq 0 \end{array}$$

Equation form

$$\begin{array}{rcl} \text{Maximize} & x_1 & + x_2 & & & = & 1 \\ & -x_1 & + x_2 & + x_3 & & = & 3 \\ & x_1 & & & + x_4 & & = & 2 \\ & & x_2 & & & + x_5 & = & 2 \\ & & & & & x_1, x_2, x_3, x_4, x_5 & \geq & 0 \end{array}$$

Simplex tableau

$$\begin{array}{rcl} x_3 & = & 1 + x_1 - x_2 \\ x_4 & = & 3 - x_1 \\ x_5 & = & 2 - x_2 \\ \hline z & = & x_1 + x_2 \end{array}$$

Example: Pivot step

Simplex tableau

$$\begin{array}{rcl} x_3 & = & 1 + x_1 - x_2 \\ x_4 & = & 3 - x_1 \\ x_5 & = & 2 - x_2 \\ \hline z & = & x_1 + x_2 \end{array}$$

Basis

- Original basis  $B = \{3, 4, 5\}$
- $x_2$  enters the basis (by our choice).
- $(0, r, 1 - r, 3, 2 - r)$  is feasible for  $r \leq 1$  since  $x_3 = 1 - r \geq 0$ .
- Therefore,  $x_3$  leaves the basis.
- New basis  $B = \{2, 4, 5\}$

New simplex tableau

$$\begin{array}{rcl} x_2 & = & 1 + x_1 - x_3 \\ x_4 & = & 3 - x_1 \\ x_5 & = & 1 - x_1 + x_3 \\ \hline z & = & 1 + 2x_1 - x_3 \end{array}$$

### Example: Next step

#### Simplex tableau

$$\begin{array}{rcl} x_2 & = & 1 + x_1 - x_3 \\ x_4 & = & 3 - x_1 \\ x_5 & = & 1 - x_1 + x_3 \\ z & = & 1 + 2x_1 - x_3 \end{array}$$

#### Next pivot

- Basis  $B = \{2, 4, 5\}$  with a basic feasible solution  $(0, 1, 0, 3, 1)$ .
- This vertex has two incident edges but only one increases the objective function.
- The edge increasing objective function is  $(t, 1+t, 0, 3-t, 1-t)$ .
- Feasible solutions for  $x_2 = 1+t \geq 0$  and  $x_4 = 3-t \geq 0$  and  $x_5 = 1-t \geq 0$ .
- Therefore,  $x_1$  enters the basis and  $x_5$  leaves the basis.

#### New simplex tableau

$$\begin{array}{rcl} x_1 & = & 1 + x_3 - x_5 \\ x_2 & = & 2 - x_5 \\ x_4 & = & 2 - x_3 + x_5 \\ z & = & 3 + x_3 - 2x_5 \end{array}$$

### Example: Optimal solution

#### Simplex tableau

$$\begin{array}{rcl} x_1 & = & 3 - x_4 \\ x_2 & = & 2 - x_5 \\ x_3 & = & 2 - x_4 + x_5 \\ z & = & 5 - x_4 - x_5 \end{array}$$

#### No other pivot

- Basis  $B = \{1, 2, 3\}$  with a basic feasible solution  $(3, 2, 2, 0, 0)$ .
- This vertex has two incident edges but no one increases the objective function.
- We have an optimal solution.

#### Why this is an optimal solution?

- Consider an arbitrary feasible solution  $\tilde{y}$ .
- The value of objective function is  $\tilde{z} = 5 - \tilde{y}_4 - \tilde{y}_5$ .
- Since  $\tilde{y}_4, \tilde{y}_5 \geq 0$ , the objective value is  $\tilde{z} = 5 - \tilde{y}_4 - \tilde{y}_5 \leq 5 = z$ .

- Since a matrix  $A_B$  is regular, we can multiply an equation  $A_B x_B + A_N x_N = b$  by  $A_B^{-1}$  to obtain  $x_B = A_B^{-1} b - A_B^{-1} A_N x_N$ , so  $Q = -A_B^{-1} A_N$  and  $p = A_B^{-1} b$ .
- The objective function is  $c_B^T x_B + c_N^T x_N = c_B^T (A_B^{-1} b - A_B^{-1} A_N x_N) + c_N^T x_N = c_B^T A_B^{-1} b + (c_N^T - c_B^T A_B^{-1} A_N) x_N$ , so  $z_0 = c_B^T A_B^{-1} b$  and  $r = c_N - (c_B^T A_B^{-1} A_N)^T$ .

- The opposite implication may not hold for a degenerated optimal basis.

### Example: Last step

#### Simplex tableau

$$\begin{array}{rcl} x_1 & = & 1 + x_3 - x_5 \\ x_2 & = & 2 - x_5 \\ x_4 & = & 2 - x_3 + x_5 \\ z & = & 3 + x_3 - 2x_5 \end{array}$$

#### Next pivot

- Basis  $B = \{1, 2, 4\}$  with a basic feasible solution  $(1, 2, 0, 2, 0)$ .
- This vertex has two incident edges but only one increases the objective function.
- The edge increasing objective function is  $(1+t, 2, t, 2-t, 0)$ .
- Feasible solutions for  $x_1 = 1+t \geq 0$  and  $x_2 = 2 \geq 0$  and  $x_4 = 2-t \geq 0$ .
- Therefore,  $x_3$  enters the basis and  $x_4$  leaves the basis.

#### New simplex tableau

$$\begin{array}{rcl} x_1 & = & 3 - x_4 \\ x_2 & = & 2 - x_5 \\ x_3 & = & 2 - x_4 + x_5 \\ z & = & 5 - x_4 - x_5 \end{array}$$

### Simplex tableau in general

#### Definition

A simplex tableau determined by a feasible basis  $B$  is a system of  $m+1$  linear equations in variables  $x_1, \dots, x_n$ , and  $z$  that has the same set of solutions as the system  $Ax = b$ ,  $z = c^T x$ , and in matrix notation looks as follows:

$$\begin{array}{rcl} x_B & = & p + Qx_N \\ z & = & z_0 + r^T x_N \end{array}$$

where  $x_B$  is the vector of the basic variables,  $x_N$  is the vector on non-basic variables,  $p \in \mathbb{R}^m$ ,  $r \in \mathbb{R}^{n-m}$ ,  $Q$  is an  $m \times (n-m)$  matrix, and  $z_0 \in \mathbb{R}$ .

#### Observation

For each basis  $B$  there exists exactly one simplex tableau, and it is given by

- $Q = -A_B^{-1} A_N$
- $p = A_B^{-1} b$  ①
- $z_0 = c_B^T A_B^{-1} b$
- $r = c_N - (c_B^T A_B^{-1} A_N)^T$  ②

### Properties of a simplex tableau

#### Simplex tableau in general

$$\begin{array}{rcl} x_B & = & p + Qx_N \\ z & = & z_0 + r^T x_N \end{array}$$

#### Observation

Basis  $B$  is feasible if and only if  $p \geq 0$ .

#### Observation

The solution corresponding to a basis  $B$  is optimal if  $r \leq 0$ . ①

#### Observation

If a linear programming problem in the equation form is feasible and bounded, then it has an optimal basic solution.

### Pivot step

#### Simplex tableau in general

$$\begin{array}{rcl} x_B & = & p + Qx_N \\ z & = & z_0 + r^T x_N \end{array}$$

#### Find a pivot

- If  $r \leq 0$ , then we have an optimal solution.
- Otherwise, choose an arbitrary entering variable  $x_v$  such that  $r_v > 0$ .
- If  $Q_{u,v} \geq 0$ , then the corresponding edge is unbounded and the problem is also unbounded. ①
- Otherwise, find a leaving variable  $x_u$  which limits the increment of the entering variable most strictly, i.e.  $Q_{u,v} < 0$  and  $-\frac{p_u}{Q_{u,v}}$  is minimal.

#### Update the simplex tableau

Gaussian elimination: Express  $x_v$  from the row  $x_u = p_u + Q_{u,v} x_v$  and substitute  $x_v$  using the obtained formula.

- Consider the following edge:  $x_v = t$ , remaining nonbasic variables are 0, and  $x_B = p + Q_{x,v}t$ . All solutions on this edge are feasible for  $t \geq 0$  since  $x \geq 0$ . For the objective value,  $c^T x = z_0 + r^T x_N = z_0 + r_v t \rightarrow \infty$  as  $t \rightarrow \infty$ , so the objective function is unbounded.

## Initial feasible basis

### Equation form

Maximize  $c^T x$  such that  $Ax = b$  and  $x \geq 0$ .

### Auxiliary linear program

- Multiply every row  $j$  with  $b_j < 0$  by  $-1$ . ①
- Introduce new variables  $y \in \mathbb{R}^m$  and solve an auxiliary linear program: Maximize  $-1^T y$  such that  $Ax + Iy = b$  and  $x \geq 0, y \geq 0$ .
- An initial basis contains variables  $y$  and an initial tableau is

$$\begin{array}{r} y = b + Ax \\ z = -1^T b + (1^T A)x \end{array}$$

- Whenever a variable of  $y$  become nonbasic, it can be removed from a tableau.
- When all variables of  $y$  are removed, express the original objective function  $c^T x$  using nonbasic variables and solve the problem.

### Observation

The original linear program has a feasible solution if and only if an optimal solution of the auxiliary linear program satisfies  $y = 0$ .

## Complexity

### Degeneracy

- Different bases may correspond to the same solution. ①
- The simplex method may loop forever between these bases.
- Bland's or lexicographic rules prevent visiting the same basis twice.

### The number of visited vertices

- The total number of vertices is finite since the number of bases is finite.
- The objective value of visited vertices is increasing, so every vertex is visited at most once. ②
- The number of visited vertices may be exponential, e.g. the Klee-Minty cube. ③
- Practical linear programming problems in equation forms with  $m$  equations typically need between  $2m$  and  $3m$  pivot steps to solve.

### Open problem

Is there a pivot rule which guarantees a polynomial number of steps?

## Outline

- Linear programming
- Linear, affine and convex sets
- Convex polyhedron
- Simplex method
- Duality of linear programming
- Ellipsoid method
- Matching

## Pivot rules

### Pivot rules

- Largest coefficient** Choose an improving variable with the largest coefficient.
- Largest increase** Choose an improving variable that leads to the largest absolute improvement in  $z$ .
- Steepest edge** Choose an improving variable whose entering into the basis moves the current basic feasible solution in a direction closest to the direction of the vector  $c$ , i.e.
 
$$\frac{c^T(x_{new} - x_{old})}{\|x_{new} - x_{old}\|}$$
- Bland's rule** Choose an improving variable with the smallest index, and if there are several possibilities of the leaving variable, also take the one with the smallest index.
- Random edge** Select the entering variable uniformly at random among all improving variables.

- Now, assume that  $b \geq 0$ .

- For example, the apex of the 3-dimensional  $k$ -side pyramid belongs to  $k$  faces, so there are  $\binom{k}{3}$  bases determining the apex.
- In degeneracy, the simplex method stay in the same vertex; and when the vertex is left, it is not visited again.
- The Klee-Minty cube is a "deformed"  $n$ -dimensional cube with  $2n$  facets and  $2^n$  vertices. The Dantzig's original pivot rule (largest coefficient) visits all vertices of this cube.

## Duality of linear programming: Example

### Find an upper bound for the following problem

$$\begin{array}{ll} \text{Maximize} & 2x_1 + 3x_2 \\ \text{subject to} & 4x_1 + 8x_2 \leq 12 \\ & 2x_1 + x_2 \leq 3 \\ & 3x_1 + 2x_2 \leq 4 \\ & x_1, x_2 \geq 0 \end{array}$$

### Simple estimates

- $2x_1 + 3x_2 \leq 4x_1 + 8x_2 \leq 12$  ①
- $2x_1 + 3x_2 \leq \frac{1}{2}(4x_1 + 8x_2) \leq 6$  ②
- $2x_1 + 3x_2 = \frac{1}{3}(4x_1 + 8x_2 + 2x_1 + x_2) \leq 5$  ③

### What is the best combination of conditions?

Every non-negative linear combination of inequalities which gives an inequality  $d_1 x_1 + d_2 x_2 \leq h$  with  $d_1 \geq 2$  and  $d_2 \geq 3$  provides the upper bound  $2x_1 + 3x_2 \leq d_1 x_1 + d_2 x_2 \leq h$ .

- 1 The first condition
- 2 A half of the first condition
- 3 A third of the sum of the first and the second conditions

- 1 The primal optimal solution is  $\mathbf{x}^T = (\frac{5}{9}, \frac{5}{4})$  and the dual solution is  $\mathbf{y}^T = (\frac{5}{16}, 0, \frac{1}{4})$ , both with the same objective value 4.75.

## Dualization

Every linear programming problem has its dual, e.g.

- Maximize  $\mathbf{c}^T \mathbf{x}$  subject to  $\mathbf{Ax} \geq \mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$  — Primal program
- Maximize  $\mathbf{c}^T \mathbf{x}$  subject to  $-\mathbf{Ax} \leq -\mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$  — Equivalent formulation
- Minimize  $-\mathbf{b}^T \mathbf{y}$  subject to  $-\mathbf{A}^T \mathbf{y} \geq \mathbf{c}$  and  $\mathbf{y} \geq \mathbf{0}$  — Dual program
- Minimize  $\mathbf{b}^T \mathbf{y}$  subject to  $\mathbf{A}^T \mathbf{y} \geq \mathbf{c}$  and  $\mathbf{y} \leq \mathbf{0}$  — Simplified formulation

A dual of a dual problem is the (original) primal problem

- Minimize  $\mathbf{b}^T \mathbf{y}$  subject to  $\mathbf{A}^T \mathbf{y} \geq \mathbf{c}$  and  $\mathbf{y} \geq \mathbf{0}$  — Dual program
- -Maximize  $-\mathbf{b}^T \mathbf{y}$  subject to  $\mathbf{A}^T \mathbf{y} \geq \mathbf{c}$  and  $\mathbf{y} \geq \mathbf{0}$  — Equivalent formulation
- -Minimize  $\mathbf{c}^T \mathbf{x}$  subject to  $\mathbf{Ax} \geq -\mathbf{b}$  and  $\mathbf{x} \leq \mathbf{0}$  — Dual of the dual program
- -Minimize  $-\mathbf{c}^T \mathbf{x}$  subject to  $-\mathbf{Ax} \geq -\mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$  — Simplified formulation
- Maximize  $\mathbf{c}^T \mathbf{x}$  subject to  $\mathbf{Ax} \leq \mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$  — The original primal program

## Linear programming: Feasibility versus optimality

### Feasibility versus optimality

Finding a feasible solution of a linear program is computationally as difficult as finding an optimal solution.

### Using duality

The optimal solutions of linear programs

- Primal: Maximize  $\mathbf{c}^T \mathbf{x}$  subject to  $\mathbf{Ax} \leq \mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$
- Dual: Minimize  $\mathbf{b}^T \mathbf{y}$  subject to  $\mathbf{A}^T \mathbf{y} \geq \mathbf{c}$  and  $\mathbf{y} \geq \mathbf{0}$

are exactly feasible solutions satisfying

$$\begin{aligned} \mathbf{Ax} &\leq \mathbf{b} \\ \mathbf{A}^T \mathbf{y} &\geq \mathbf{c} \\ \mathbf{c}^T \mathbf{x} &\geq \mathbf{b}^T \mathbf{y} \\ \mathbf{x}, \mathbf{y} &\geq \mathbf{0} \end{aligned}$$

## Duality of linear programming: Example

Consider a non-negative combination  $\mathbf{y}$  of inequalities

$$\begin{aligned} \text{Maximize} \quad & 2\mathbf{x}_1 + 3\mathbf{x}_2 \\ \text{subject to} \quad & 4\mathbf{x}_1 + 8\mathbf{x}_2 \leq 12 \quad / \cdot \mathbf{y}_1 \\ & 2\mathbf{x}_1 + \mathbf{x}_2 \leq 3 \quad / \cdot \mathbf{y}_2 \\ & 3\mathbf{x}_1 + 2\mathbf{x}_2 \leq 4 \quad / \cdot \mathbf{y}_3 \\ & \mathbf{x}_1, \mathbf{x}_2 \geq 0 \end{aligned}$$

### Observations

- Every feasible solution  $\mathbf{x}$  and non-negative combination  $\mathbf{y}$  satisfies  $(4\mathbf{y}_1 + 2\mathbf{y}_2 + 3\mathbf{y}_3)\mathbf{x}_1 + (8\mathbf{y}_1 + \mathbf{y}_2 + 2\mathbf{y}_3)\mathbf{x}_2 \leq 12\mathbf{y}_1 + 3\mathbf{y}_2 + 4\mathbf{y}_3$ .
- If  $4\mathbf{y}_1 + 2\mathbf{y}_2 + 3\mathbf{y}_3 \geq 2$  and  $8\mathbf{y}_1 + \mathbf{y}_2 + 2\mathbf{y}_3 \geq 3$ , then  $12\mathbf{y}_1 + 3\mathbf{y}_2 + 4\mathbf{y}_3$  is an upper for the objective function.

### Dual program

$$\begin{aligned} \text{Minimize} \quad & 12\mathbf{y}_1 + 2\mathbf{y}_2 + 4\mathbf{y}_3 \\ \text{subject to} \quad & 4\mathbf{y}_1 + 2\mathbf{y}_2 + 3\mathbf{y}_3 \geq 2 \\ & 8\mathbf{y}_1 + \mathbf{y}_2 + 2\mathbf{y}_3 \geq 3 \\ & \mathbf{y}_1, \mathbf{y}_2, \mathbf{y}_3 \geq 0 \end{aligned}$$

## Duality of linear programming: General

### Primal linear program

Maximize  $\mathbf{c}^T \mathbf{x}$  subject to  $\mathbf{Ax} \leq \mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$

### Dual linear program

Minimize  $\mathbf{b}^T \mathbf{y}$  subject to  $\mathbf{A}^T \mathbf{y} \geq \mathbf{c}$  and  $\mathbf{y} \geq \mathbf{0}$

### Weak duality theorem

For every primal feasible solution  $\mathbf{x}$  and dual feasible solution  $\mathbf{y}$  hold  $\mathbf{c}^T \mathbf{x} \leq \mathbf{b}^T \mathbf{y}$ .

### Corollary

If one program is unbounded, then the other one is infeasible.

### Duality theorem

Exactly one of the following possibilities occurs

- 1 Neither primal nor dual has a feasible solution
- 2 Primal is unbounded and dual is infeasible
- 3 Primal is infeasible and dual is unbounded
- 4 There are feasible solutions  $\mathbf{x}$  and  $\mathbf{y}$  such that  $\mathbf{c}^T \mathbf{x} = \mathbf{b}^T \mathbf{y}$

## Dualization: General rules

	Maximizing program	Minimizing program
Variables	$\mathbf{x}_1, \dots, \mathbf{x}_n$	$\mathbf{y}_1, \dots, \mathbf{y}_m$
Matrix	$\mathbf{A}$	$\mathbf{A}^T$
Right-hand side	$\mathbf{b}$	$\mathbf{c}$
Objective function	$\max \mathbf{c}^T \mathbf{x}$	$\min \mathbf{b}^T \mathbf{y}$
Constraints	$i$ -th constraint has $\leq$ $i$ -th constraint has $\geq$ $i$ -th constraint has $=$ $\mathbf{x}_i \geq 0$ $\mathbf{x}_i \leq 0$ $\mathbf{x}_i \in \mathbb{R}$	$\mathbf{y}_i \geq 0$ $\mathbf{y}_i \leq 0$ $\mathbf{y}_i \in \mathbb{R}$ $j$ -th constraint has $\geq$ $j$ -th constraint has $\leq$ $j$ -th constraint has $=$

## Complementary slackness

### Theorem

Feasible solutions  $\mathbf{x}$  and  $\mathbf{y}$  of linear programs

- Primal: Maximize  $\mathbf{c}^T \mathbf{x}$  subject to  $\mathbf{Ax} \leq \mathbf{b}$  and  $\mathbf{x} \geq \mathbf{0}$
- Dual: Minimize  $\mathbf{b}^T \mathbf{y}$  subject to  $\mathbf{A}^T \mathbf{y} \geq \mathbf{c}$  and  $\mathbf{y} \geq \mathbf{0}$

are optimal if and only if

- $\mathbf{x}_i = 0$  or  $\mathbf{A}_{i,*}^T \mathbf{y} = \mathbf{c}_i$  for every  $i = 1, \dots, n$  and
- $\mathbf{y}_j = 0$  or  $\mathbf{A}_{j,*} \mathbf{x} = \mathbf{b}_j$  for every  $j = 1, \dots, m$ .

### Proof

$$\mathbf{c}^T \mathbf{x} = \sum_{i=1}^n \mathbf{c}_i \mathbf{x}_i \leq \sum_{i=1}^n (\mathbf{y}^T \mathbf{A}_{i,*}) \mathbf{x}_i = \mathbf{y}^T \mathbf{Ax} = \sum_{j=1}^m \mathbf{y}_j (\mathbf{A}_{j,*} \mathbf{x}) \leq \sum_{j=1}^m \mathbf{y}_j \mathbf{b}_j = \mathbf{b}^T \mathbf{y}$$

Goal: Find a feasible solution

$$\begin{aligned} 2x - 5y + 4z &\leq 10 \\ 3x - 6y + 3z &\leq 9 \\ 5x + 10y - z &\leq 15 \\ -x + 5y - 2z &\leq -7 \\ -3x + 2y + 6z &\leq 12 \end{aligned}$$

Express the variable  $x$  in each condition

$$\begin{aligned} x &\leq 5 + \frac{5}{2}y - 2z \\ x &\leq 3 + 2y - z \\ x &\leq 3 - 2y + \frac{1}{5}z \\ x &\geq 7 + 5y - 2z \\ x &\geq -4 + \frac{2}{3}y + 2z \end{aligned}$$

Eliminate the variable  $x$

The original system has a feasible solution if and only if there exist  $y$  and  $z$  satisfying

$$\max \left\{ 7 + 5y - 2z, -4 + \frac{2}{3}y + 2z \right\} \leq \min \left\{ 5 + \frac{5}{2}y - 2z, 3 + 2y - z, 3 - 2y + \frac{1}{5}z \right\}$$

Fourier–Motzkin elimination: In general

Observation

Let  $Ax \leq b$  be a system with  $n \geq 1$  variables and  $m$  inequalities. There is a system  $A'x' \leq b'$  with  $n - 1$  variables and at most  $\max\{m, m^2/4\}$  inequalities, with the following properties:

- $Ax \leq b$  has a solution if and only if  $A'x' \leq b'$  has a solution, and
- each inequality of  $A'x' \leq b'$  is a positive linear combination of some inequalities from  $Ax \leq b$ .

Proof

- WLOG:  $A_{i,1} \in \{-1, 0, 1\}$  for all  $i = 1, \dots, m$
- Let  $C = \{i; A_{i,1} = 1\}$ ,  $F = \{i; A_{i,1} = -1\}$  and  $L = \{i; A_{i,1} = 0\}$
- Let  $A'x' \leq b'$  be the system of  $n - 1$  variables and  $|C| \cdot |F| + |L|$  inequalities

$$\begin{aligned} j \in C, k \in F: & (A_{j,*} + A_{k,*})x' \leq b_j + b_k \quad (1) \\ l \in L: & A_{l,*}x' \leq b_l \quad (2) \end{aligned}$$

- Assuming  $A'x' \leq b'$  has a solution  $x'$ , we find a solution  $x$  of  $Ax \leq b$ :
  - (1) is equivalent to  $A_{j,*}x' - b_k \leq b_j - A_{j,*}x'$  for all  $j \in C, k \in F$ ,
  - which is equivalent to  $\max_{k \in F} \{A_{j,*}x' - b_k\} \leq \min_{j \in C} \{b_j - A_{j,*}x'\}$
  - Choose  $x_1$  between these bounds and  $x = (x_1, x')$  satisfies  $Ax \leq b$

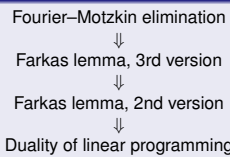

Farkas lemma

Proposition (Farkas lemma)

Let  $A \in \mathbb{R}^{m \times n}$  and  $b \in \mathbb{R}^m$ . The following statements hold.

- The system  $Ax = b$  has a non-negative solution  $x \in \mathbb{R}^n$  if and only if every  $y \in \mathbb{R}^m$  with  $y^T A \geq 0^T$  satisfies  $y^T b \geq 0$ .
- The system  $Ax \leq b$  has a non-negative solution  $x \in \mathbb{R}^n$  if and only if every non-negative  $y \in \mathbb{R}^m$  with  $y^T A \geq 0^T$  satisfies  $y^T b \geq 0$ .
- The system  $Ax \leq b$  has a solution  $x \in \mathbb{R}^n$  if and only if every non-negative  $y \in \mathbb{R}^m$  with  $y^T A = 0^T$  satisfies  $y^T b \geq 0$ .

Overview of the proof of duality

Observation (Exercise)

Variants of Farkas lemma are equivalent.

Proof of the duality of linear programming

Proposition (Farkas lemma, 2nd version)

Let  $A \in \mathbb{R}^{m \times n}$  and  $b \in \mathbb{R}^m$ . The system  $Ax \leq b$  has a non-negative solution if and only if every non-negative  $y \in \mathbb{R}^m$  with  $y^T A \geq 0^T$  satisfies  $y^T b \geq 0$ .

Duality

- Primal: Maximize  $c^T x$  subject to  $Ax \leq b$  and  $x \geq 0$
- Dual: Minimize  $b^T y$  subject to  $A^T y \geq c$  and  $y \geq 0$

If the primal problem has an optimal solution  $x^*$ , then the dual problem has an optimal solution  $y^*$  and  $c^T x^* = b^T y^*$ .

Proof of duality using Farkas lemma

- Let  $x^*$  be an optimal solution of the primal problem and  $\gamma = c^T x^*$
- $\epsilon > 0$  iff  $Ax \leq b$  and  $x \geq 0$  and  $c^T x \geq \gamma + \epsilon$  is infeasible
- $\epsilon > 0$  iff  $\begin{pmatrix} A \\ -c \end{pmatrix} x \leq \begin{pmatrix} b \\ -\gamma - \epsilon \end{pmatrix}$  and  $x \geq 0$  is infeasible
- $\epsilon > 0$  iff  $u, z \geq 0$  and  $\begin{pmatrix} A \\ -c \end{pmatrix}^T \begin{pmatrix} u \\ z \end{pmatrix} \geq 0^T$  and  $\begin{pmatrix} b \\ -\gamma - \epsilon \end{pmatrix} < 0$  is feasible
- $\epsilon > 0$  iff  $u, z \geq 0$  and  $A^T u \geq zc$  and  $b^T u < z(\gamma + \epsilon)$  is feasible

Rewrite into a system of inequalities

Real numbers  $y$  and  $z$  satisfy

$$\max \{7 + 5y - 2z, -4 + \frac{2}{3}y + 2z\} \leq \min \{5 + \frac{5}{2}y - 2z, 3 + 2y - z, 3 - 2y + \frac{1}{5}z\}$$

and only they satisfy

$$\begin{aligned} 7 + 5y - 2z &\leq 5 + \frac{5}{2}y - 2z \\ 7 + 5y - 2z &\leq 3 + 2y - z \\ 7 + 5y - 2z &\leq 3 - 2y + \frac{1}{5}z \\ -4 + \frac{2}{3}y + 2z &\leq 5 + \frac{5}{2}y - 2z \\ -4 + \frac{2}{3}y + 2z &\leq 3 + 2y - z \\ -4 + \frac{2}{3}y + 2z &\leq 3 - 2y + \frac{1}{5}z \end{aligned}$$

Overview

- Eliminate the variable  $y$ , find a feasible evaluation of  $z$  and compute  $y$  a  $x$ .
- In every step, we eliminate one variable; however, the number of conditions may increase quadratically.
- If we start with  $m$  conditions, then after  $n$  eliminations the number of conditions is up to  $4(m/4)^{2^n}$ .

Farkas lemma

Definition

A cone generated by vectors  $a_1, \dots, a_n \in \mathbb{R}^m$  is the set of all non-negative combinations of  $a_1, \dots, a_n$ , i.e.  $\{\sum_{i=1}^n \alpha_i a_i; \alpha_1, \dots, \alpha_n \geq 0\}$ .

Proposition (Farkas lemma geometrically)

Let  $a_1, \dots, a_n, b \in \mathbb{R}^m$ . Then exactly one of the following two possibilities occurs:

- The point  $b$  lies in the cone generated by  $a_1, \dots, a_n$ .
- There exists a hyperplane  $h = \{x \in \mathbb{R}^m; y^T x = 0\}$  containing  $0$  for some  $y \in \mathbb{R}^m$  separating  $a_1, \dots, a_n$  and  $b$ , i.e.  $y^T a_i \geq 0$  for all  $i = 1, \dots, n$  and  $y^T b < 0$ .

Proposition (Farkas lemma)

Let  $A \in \mathbb{R}^{m \times n}$  and  $b \in \mathbb{R}^m$ . Then exactly one of the following two possibilities occurs:

- There exists a vector  $x \in \mathbb{R}^n$  satisfying  $Ax = b$  and  $x \geq 0$ .
- There exists a vector  $y \in \mathbb{R}^m$  satisfying  $y^T A \geq 0$  and  $y^T b < 0$ .

Farkas lemma

Proposition (Farkas lemma, 3rd version)

Let  $A \in \mathbb{R}^{m \times n}$  and  $b \in \mathbb{R}^m$ . Then, the system  $Ax \leq b$  has a solution  $x \in \mathbb{R}^n$  if and only if every non-negative  $y \in \mathbb{R}^m$  with  $y^T A = 0^T$  satisfies  $y^T b \geq 0$ .

Proof (overview)

⇒ If  $x$  satisfies  $Ax \leq b$  and  $y \geq 0$  satisfies  $y^T A = 0^T$ , then  $y^T b \geq y^T Ax \geq 0^T x = 0$

⇐ If  $Ax \leq b$  has no solution, find  $y \geq 0$  satisfying  $y^T A = 0^T$  and  $y^T b < 0$  by the induction on  $n$

- $n = 0$ 
  - The system  $Ax \leq b$  equals to  $0 \leq b$  which is infeasible, so  $b_i < 0$  for some  $i$
  - Choose  $y = e_i$  (the  $i$ -th unit vector)
- $n > 0$ 
  - Using Fourier–Motzkin elimination we obtain an infeasible system  $A'x' \leq b'$
  - There exists a non-negative matrix  $M$  such that  $(0|A') = MA$  and  $b' = Mb$
  - By induction, there exists  $y' \geq 0$ ,  $y'^T A' = 0^T$ ,  $y'^T b' < 0$
  - We verify that  $y = M^T y'$  satisfies all requirements of the induction
    - $y = M^T y' \geq 0$
    - $y^T A = (M^T y')^T A = y'^T MA = y'^T (0|A') = 0^T$
    - $y^T b = (M^T y')^T b = y'^T Mb = y'^T b' < 0^T$

Proof of the duality of linear programming

Duality

- Primal: Maximize  $c^T x$  subject to  $Ax \leq b$  and  $x \geq 0$
- Dual: Minimize  $b^T y$  subject to  $A^T y \geq c$  and  $y \geq 0$

If the primal problem has an optimal solution  $x^*$ , then the dual problem has an optimal solution  $y^*$  and  $c^T x^* = b^T y^*$ .

Proof of duality using Farkas lemma (continue)

- Let  $x^*$  be an optimal solution of the primal problem and  $\gamma = c^T x^*$
- $\epsilon > 0$  iff  $u, z \geq 0$  and  $A^T u \geq zc$  and  $b^T u < z(\gamma + \epsilon)$  is feasible
- For  $\epsilon > 0$ , there exists  $u', z' \geq 0$  with  $A^T u' \geq z'c$  and  $b^T u' < z'(\gamma + \epsilon)$
- For  $\epsilon = 0$  it holds that  $u', z' \geq 0$  and  $A^T u' \geq z'c$  so  $b^T u' \geq z'\gamma$
- Since  $z'\gamma \leq b^T u' < z'(\gamma + \epsilon)$  and  $z' \geq 0$  it follows that  $z' > 0$
- Let  $v = \frac{1}{z'} u'$
- Since  $A^T v \geq c$  and  $v \geq 0$ , the dual solution  $v$  is feasible
- Since the dual is feasible and bounded, there exists an optimal dual solution  $y^*$
- Hence,  $b^T y^* < \gamma + \epsilon$  for every  $\epsilon > 0$ , and so  $b^T y^* \leq \gamma$
- From the weak duality theorem it follows that  $b^T y^* = c^T x^*$

- 1 Linear programming
- 2 Linear, affine and convex sets
- 3 Convex polyhedron
- 4 Simplex method
- 5 Duality of linear programming
- 6 Ellipsoid method**
- 7 Matching

## Ellipsoid method

## Idea

Consider an ellipsoid  $E$  containing  $Z$ . In every step, reduce the volume of  $E$  using an hyperplane provided by the oracle.

## Algorithm

```

1 Init:  $s = \mathbf{0}$ ,  $E = B(s, R)$ 
2 Loop
3   if volume of  $E$  is smaller than volume of  $B(\mathbf{0}, \epsilon)$  then
4     return  $Z$  is empty
5   Call the oracle
6   if  $s \in Z$  then
7     return  $s$  is a point of  $Z$ 
8   Update  $s$  and  $Z$  using the separation hyperplane found by oracle

```

## Ellipsoid method: update of the ellipsoid

## Separation hyperplane

Consider a hyperplane  $\mathbf{a}^T \mathbf{x} = b$  such that  $\mathbf{a}^T \mathbf{s} \geq b$  and  $Z \subseteq \{\mathbf{x}; \mathbf{a}^T \mathbf{x} \leq b\}$ . For simplicity, assume that the hyperplane contains  $\mathbf{s}$ , that is  $\mathbf{a}^T \mathbf{s} = b$ .

## Update formulas (without proof)

$$\mathbf{s}' = \mathbf{s} - \frac{1}{n+1} \frac{Q\mathbf{a}}{\sqrt{\mathbf{a}^T Q \mathbf{a}}}$$

$$Q' = \frac{n^2}{n^2 - 1} \left( Q - \frac{2}{n+1} \frac{Q\mathbf{a}\mathbf{a}^T Q}{\mathbf{a}^T Q \mathbf{a}} \right)$$

## Reduce of the volume (without proof)

$$\frac{\text{volume}(E')}{\text{volume}(E)} \leq e^{-\frac{1}{2n+2}}$$

## Corollary

The number of steps of the Ellipsoid method is at most  $\lceil n(2n+2) \ln \frac{n}{\epsilon} \rceil$ .

## Strongly polynomial algorithm for linear programming

## Ellipsoid method is not strongly polynomial (without proof)

For every  $M$  there exists a linear program with 2 variables and 2 constrains such that the ellipsoid method executes at least  $M$  mathematical operations.

## Open problem

Decide whether there exist an algorithm for linear programming which is polynomial in the number of variables and constrains.

## Problem

Determine whether a given fully-dimensional convex compact set  $Z \subseteq \mathbb{R}^n$  (e.g. a polytope) is non-empty and find a point in  $Z$  if exists.

## Separation oracle

Separation oracle determines whether a point  $s$  belongs into  $Z$ . If  $s \notin Z$ , the oracle finds a hyperplane that separates  $s$  and  $Z$ .

## Inputs

- Radius  $R > 0$  of a ball  $B(\mathbf{0}, R)$  containing  $Z$
- Radius  $\epsilon > 0$  such that  $Z$  contains  $B(s, \epsilon)$  for some point  $s$  if  $Z$  is non-empty
- Separation oracle

## Ellipsoid

## Definition: Ball

The ball in the centre  $\mathbf{s} \in \mathbb{R}^n$  and radius  $R \geq 0$  is  $B(\mathbf{s}, R) = \{\mathbf{x} \in \mathbb{R}^n; \|\mathbf{x} - \mathbf{s}\| \leq R\}$ .

## Definition

Ellipsoid  $E$  is an affine transformation of the unit ball  $B(\mathbf{0}, 1)$ . That is,  $E = \{M\mathbf{x} + \mathbf{s}; \mathbf{x} \in B(\mathbf{0}, 1)\}$  where  $M$  is a regular matrix and  $\mathbf{s}$  is the centre of  $E$ .

## Notation

$$E = \{\mathbf{y} \in \mathbb{R}^n; M^{-1}(\mathbf{y} - \mathbf{s}) \in B(\mathbf{0}, 1)\}$$

$$= \{\mathbf{y} \in \mathbb{R}^n; (\mathbf{y} - \mathbf{s})^T (M^{-1})^T M^{-1} (\mathbf{y} - \mathbf{s}) \leq 1\}$$

$$= \{\mathbf{y} \in \mathbb{R}^n; (\mathbf{y} - \mathbf{s})^T Q^{-1} (\mathbf{y} - \mathbf{s}) \leq 1\}$$

where  $Q = MM^T$  is a positive definite matrix

## Ellipsoid method: Estimation of radii for rational polytopes

Largest coefficient of  $A$  and  $\mathbf{b}$ 

Let  $L$  be the maximal absolute value of all coefficients of  $A$  and  $\mathbf{b}$ .

Estimation of  $R$ 

We find  $R'$  such that  $\|\mathbf{x}\|_\infty \leq R'$  for all  $\mathbf{x}$  satisfying  $A\mathbf{x} \leq \mathbf{b}$ :

- Consider a vertex of the polytope satisfying a subsystem  $A'\mathbf{x} = \mathbf{b}'$
- Cramer's rule:  $x_i = \frac{\det A'_i}{\det A'}$
- $|\det(A'_i)| \leq n!L^n$  using the definition of determinant
- $|\det(A')| \geq 1$  since  $A'$  is integral and regular

From the choice  $R' = n!L^n$ , it follows that  $\log(R) = O(n^2 \log(n) \log(L))$

Estimation of  $\epsilon$  (without proof)

A non-empty rational fully-dimensional polytope contains a ball with radius  $\epsilon$  where  $\log \frac{1}{\epsilon} = O(\text{poly}(n, m, \log L))$ .

## Complexity of Ellipsoid method

Time complexity of Ellipsoid method is polynomial in the length of binary encoding of  $A$  and  $\mathbf{b}$ .

## Augmenting paths

### Definitions

Let  $M \subseteq E$  a matching of a graph  $G = (V, E)$ .

- A vertex  $v \in V$  is *M-covered* if some edge of  $M$  is incident with  $v$ .
- A vertex  $v \in V$  is *M-exposed* if  $v$  is not *M-covered*.
- A path  $P$  is *M-alternating* if its edges are alternately in and not in  $M$ .
- An *M-alternating* path is *M-augmenting* if both end-vertices are *M-exposed*.

### Augmenting path theorem of matchings

A matching  $M$  in a graph  $G = (V, E)$  is maximum if and only if there is no *M-augmenting* path.

### Proof

⇒ Every *M-augmenting* path increases the size of  $M$

⇐ Let  $N$  be a matching such that  $|N| > |M|$  and we find an *M-augmenting* path

- ① The graph  $(V, N \cup M)$  contains a component  $K$  which has more  $N$  edges than  $M$  edges
- ②  $K$  has at least two vertices  $u$  and  $v$  which are  $N$ -covered and  $M$ -exposed
- ③ Vertices  $u$  and  $v$  are joined by a path  $P$  in  $K$
- ④ Observe that  $P$  is *M-augmenting*

Jirka Fink

Optimization methods

91

- ① A component of a graph is odd if it has odd number of vertices.
- ② Every odd component has at least one exposed vertex.
- ③ ⇒ If a graph  $G$  has a perfect matching, then  $\text{def}(G) = 0$ , so from the previous observation it follows that  $\text{oc}(G \setminus A) \leq |A|$ .
- ⇐ We will present an algorithmic proof which finds a perfect matching or a subset  $A \subseteq V$  such that  $\text{oc}(G \setminus A) > |A|$ .

Jirka Fink

Optimization methods

92

- ① An *M-alternating* tree  $T$  with the root  $r$  on vertices  $A$  and  $B$  is a tree obtained from this initialization by applying the following operation extend.

- ① In the perfect matching problem, we can add a constant to weights of all edges without changing the set of all optimal perfect matchings. Therefore, if some edge has a negative weight, we can add a sufficiently large constant to all weights to ensure non-negativity of  $c$ .

Jirka Fink

Optimization methods

90

## Tutte-Berge Formula

### Definitions

- Let  $\text{def}(G)$  be the number of exposed vertices by a maximum size matching in  $G$ .
- Let  $\text{oc}(G)$  be the number of odd components of a graph  $G$ . ①

### Observations

- $\text{def}(G) \geq \text{oc}(G)$
- For every  $A \subseteq V$  it holds that  $\text{def}(G) \geq \text{oc}(G \setminus A) - |A|$ . ②

### Tutte's matching theorem

A graph  $G$  has a perfect matching if and only if  $\text{oc}(G \setminus A) \leq |A|$  for every  $A \subseteq V$ . ③

### Theorem: Tutte-Berge Formula (without proof)

$\text{def}(G) = \max \{ \text{oc}(G \setminus A) - |A|; A \subseteq V \}$

Jirka Fink

Optimization methods

92

## Building an alternating tree

### Initialization of *M-alternating* tree $T$ on vertices $A \cup B$

$T = A = \emptyset$  and  $B = \{r\}$  where  $r$  is an *M-exposed* root. ①

### Use $uv \in E$ to extend $T$

Input: An edge  $uv \in E$  such that  $u \in B$  and  $v \notin A \cup B$  and  $v$  is *M-covered*.

Action: Let  $vz \in M$  and extend  $T$  by edges  $\{uv, vz\}$  and  $A$  by  $v$  and  $B$  by  $z$ .

### Properties

- $r$  is the only *M-exposed* vertex of  $T$ .
- For every  $v$  of  $T$ , the path in  $T$  from  $v$  to  $r$  is *M-alternating*.
- $|B| = |A| + 1$

### Use $uv \in E$ to augment $M$

Input: An edge  $uv \in E$  such that  $u \in B$  and  $v \notin A \cup B$  and  $v$  is *M-exposed*.

Action: Let  $P$  be the path obtained by attaching  $uv$  to the path from  $r$  to  $u$  in  $T$ . Replace  $M$  by  $M \Delta E(P)$ .

Jirka Fink

Optimization methods

93

## Frustrated tree

### Definition

*M-alternating* tree  $T$  is *M-frustrated* if every edge of  $G$  having one end vertex in  $B$  has the other end vertex in  $A$ . ①

### Observation

If a bipartite graph  $G$  has a matching  $M$  and an frustrated *M-alternating* tree, then  $G$  has no perfect matching. ② ③

Jirka Fink

Optimization methods

93

Jirka Fink

Optimization methods

94

① That is, an  $M$ -alternating tree is frustrated if neither operation extend nor augment can be applied. Note that in bipartite graphs, there is no edge between vertices of  $B$ .

②  $B$  are single vertex components in the graph  $G \setminus A$ . Therefore,  $oc(G \setminus A) \geq |B| > |A|$ .

③ This proves that Tutte's matching theorem for bipartite graphs: From every  $M$ -exposed vertex  $r$  we build an  $M$ -alternating tree  $T$  such that  $T$  can be used to augment  $M$  to cover  $r$  or  $T$  is frustrated.

- ① Actually, it suffices to once iterate over all vertices.
- ② That is, the augmentation was no applied.

## Weighted perfect matchings in a bipartite graph: Overview

### Complementary slackness

$x_{uv} = 0$  or  $y_u + y_v = c_{uv}$  for every edge  $uv \in E$ , that is  $M_x \subseteq E_y$ .

### Invariants

- $x \in \{0, 1\}^E$  and  $M_x = \{uv \in E; x_{uv} = 1\}$  forms a matching.
- Dual solution is feasible, that is  $y_u + y_v \leq c_{uv}$ .
- Every matching edge is tight, that is  $M_x \subseteq E_y$ .

### Initial solution satisfying invariants

$x = \mathbf{0}$  and  $y = \mathbf{0}$

### Lemma: optimality

If  $M_x$  is a perfect matching, then  $M_x$  is a perfect matching with the minimum weight.

### Idea of the algorithm

- If there exists an  $M_x$ -augmenting path  $P$  in  $(V, E_y)$ , then use  $P$  to augment  $M_x$ .
- Otherwise, use a frustrated  $M_x$ -alternating tree in  $(V, E_y)$  to update the dual solution  $y$  and enlarge  $E_y$ .

- ① Note that  $T$  uses only tight edges.
- ② Invariants are satisfied since  $M$  is augmented by edges of  $T$  which are tight.
- ③ Observe that  $y$  remains a dual feasible solution. Furthermore, no edge is removed from the tight set  $E_y$  and at least one edge become tight. Therefore, all invariants remain satisfied.
- ④ In the next iteration, an edge  $uv$  minimizing  $\epsilon$  is used to extend  $T$  or augment  $M$ .
- ⑤  $T$  is a frustrated  $M$ -alternating tree in  $G$ . Also note that the dual problem is unbounded since  $\epsilon$  is unbounded in this case.

## Algorithm for perfect matching problem in a bipartite graph

### Algorithm

```

1 Init:  $M := \emptyset$ 
2 while  $G$  contains an  $M$ -exposed vertex  $r$  ⊙ do
3    $A := \emptyset$  and  $B = \{r\}$  # Build an  $M$ -alternating tree from  $r$ .
4   while there exists  $uv \in E$  with  $u \in B$  and  $v \notin A \cup B$  do
5     if  $v$  is  $M$ -covered then
6       Use  $uv$  to extend  $T$ 
7     else
8       Use  $uv$  to augment  $M$ 
9       break # Terminate the inner loop.
10  if  $r$  is still  $M$ -exposed ⊙ then
11    return There is no perfect matching #  $T$  is a frustrated tree.
12 return Perfect matching  $M$ 

```

### Theorem

The algorithm decides whether a given bipartite graph  $G$  has a perfect matching and find one if exists. The algorithm calls  $O(n)$  augmenting operations and  $O(n^2)$  extending operations.

## Duality and complementary slackness of perfect matchings

### Primal: relaxed perfect matching

Minimize  $c^T x$  subject to  $Ax = \mathbf{1}$  and  $x \geq \mathbf{0}$  where  $A$  is the incidence matrix.

### Dual

Maximize  $\mathbf{1}^T y$  subject to  $A^T y \leq c$  and  $y \in \mathbb{R}^E$ , that is  $y_u + y_v \leq c_{uv}$ .

### Idea of primal-dual algorithms

If we find a primal and a dual feasible solutions satisfying the complementary slackness, then solutions are optimal (relaxed) solutions.

### Definition

- An edge  $uv \in E$  is called *tight* if  $y_u + y_v = c_{uv}$ .
- Let  $E_y$  be the set of a tight edges of the dual solution  $y$ .
- Let  $M_x = \{uv \in E; x_{uv} = 1\}$  be the set of matching edge of the primal solution  $x$ .

### Complementary slackness

$x_{uv} = 0$  or  $y_u + y_v = c_{uv}$  for every edge  $uv \in E$ , that is  $M_x \subseteq E_y$ .

## Algorithm for minimum weight perfect matchings in a bipartite graph

### Algorithm

```

1 Init:  $M := \emptyset$  and  $y = \mathbf{0}$ 
2 while  $G$  contains an  $M$ -exposed vertex  $r$  do
3    $A := \emptyset$  and  $B = \{r\}$  # Build an  $M$ -alternating tree from  $r$ .
4   while  $r$  is  $M$ -exposed do
5     if there exists  $uv \in E_y$  with  $u \in B$  and  $v \notin A \cup B$  then
6       if  $v$  is  $M$ -covered then
7         Use  $uv$  to extend  $T$  ⊙
8       else
9         Use  $uv$  to augment  $M$  ⊙
10    else if there exists  $uv \in E$  with  $u \in B$  and  $v \notin A \cup B$  then
11       $\epsilon = \min \{c_{uv} - y_u - y_v; u, v \in E, u \in B, v \notin A \cup B\}$ 
12       $y_u := y_u + \epsilon$  for all  $u \in B$ 
13       $y_v := y_v - \epsilon$  for all  $v \in A$  ⊙ ⊙
14    else
15      return There is no perfect matching in  $G$ . ⊙
16 return Minimum weight perfect matching  $M$ 

```

## Algorithm for minimum weight perfect matchings in a bipartite graph

### Theorem

The algorithm decides whether a given bipartite graph  $G$  has a perfect matching and a minimal-weight perfect matching if exists. The algorithm calls  $O(n)$  augmenting operations and  $O(n^2)$  extending operations and  $O(n^2)$  dual changes.

## Shrinking odd circuits

### Definition

Let  $C$  be an odd circuit in  $G$ . The graph  $G \times C$  has vertices  $(V(G) \setminus V(C)) \cup \{c'\}$  where  $c'$  is a new vertex and edges  $\odot$

- $E(G)$  with both end-vertices in  $V(G) \setminus V(C)$  and
- and  $uc'$  for every edge  $uv$  with  $u \notin V(C)$  and  $v \in V(C)$ .

Edges  $E(C)$  are removed.

### Proposition

Let  $C$  be an odd circuit of  $G$  and  $M'$  be a matching  $G \times C$ . Then, there exists a matching  $M$  of  $G$  such that  $M \subseteq M' \cup E(C)$  and the number of  $M'$ -exposed nodes of  $G$  is the same as the number of  $M'$ -exposed nodes in  $G \times C$ .

### Corollary

$\text{def}(G) \leq \text{def}(G \times C)$

### Remark

There exists a graph  $G$  with odd circuit  $C$  such that  $\text{def}(G) < \text{def}(G \times C)$ .

## Perfect matching in general graphs

### Use $uv$ to shrink and update $M'$ and $T$

**Input:** A matching  $M'$  of a graph  $G'$ , an  $M'$ -alternating tree  $T$ , edge  $uv \in E'$  such that  $u, v \in B$

**Action:** Let  $C$  be the circuit formed by  $uv$  together with the path in  $T$  from  $u$  to  $v$ . Replace

- $G'$  by  $G' \times C$
- $M'$  by  $M' \setminus E(C)$
- $T$  by the tree having edge-set  $E(T) \setminus E(C)$ .

### Observation

Let  $G'$  be a graph obtained from  $G$  by a sequence of odd-circuit shrinkings. Let  $M'$  be a matching of  $G'$  and let  $T$  be an  $M'$ -alternating tree of  $G'$  such that all vertices of  $A$  are original vertices of  $G$ . If  $T$  is frustrated, then  $G$  has no perfect matching.

### Proof is based on Tutte's matching theorem

A graph  $G$  has a perfect matching if and only if  $oc(G \setminus A) \leq |A|$  for every  $A \subseteq V$ .

## Perfect matchings algorithm in a non-weighted graph II

### Algorithm

```

1 Init:  $M' := \emptyset, G' = G$ 
2 while  $G'$  contains an  $M'$ -exposed vertex  $r$  do
3    $T = (\{r\}, \emptyset)$ 
4   while  $r$  is  $M'$ -exposed do
5     if there exists  $uv \in E(G')$  with  $u \in B$  and  $v \notin A$  then
6       if  $v \in B$  then
7         Use  $uv$  to shrink and update  $M'$  and  $T$ 
8       else if  $v$  is  $M'$ -covered then
9         Use  $uv$  to extend  $T$ 
10      else
11        Use  $uv$  to augment  $M'$ 
12      else if there exists a pseudonode  $u$  in  $A$  then
13        Expand  $u$  into a circuit and update  $T, M'$  and  $G'$ 
14      else
15        return There is no perfect matching
16 Expand all pseudonodes and obtain  $M$  from  $M'$ 
17 return Perfect matching  $M$ 

```

## Minimum-Weight perfect matchings in general graphs: Duality

### Primal

Minimize  $\mathbf{c}\mathbf{x}$   
 subject to  $\delta^u \mathbf{x} = 1$  for all  $u \in V$   
 $\delta^D \mathbf{x} \geq 1$  for all  $D \in \mathcal{C}$   
 $\mathbf{x} \geq \mathbf{0}$

### Dual

Maximize  $\sum_{v \in V} \mathbf{y}_v + \sum_{D \in \mathcal{C}} \mathbf{z}_D$   
 subject to  $\mathbf{y}_u + \mathbf{y}_v + \sum_{D \in \mathcal{C}} \mathbf{z}_D \leq \mathbf{c}_{uv}$  for all  $uv \in E$   
 $\mathbf{z} \geq \mathbf{0}$

### Notation: Reduced cost

$\bar{\mathbf{c}}_{uv} := \mathbf{c}_{uv} - \mathbf{y}_u - \mathbf{y}_v - \sum_{D \in \mathcal{C}} \mathbf{z}_D$   
 An edge  $e$  is tight if  $\bar{\mathbf{c}}_e = 0$  and let  $E_t$  be the set of tight edges.

### Complementary slackness

- $\mathbf{x}_e > 0$  implies  $e$  is tight for all  $e \in E$
- $\mathbf{z}_D > 0$  implies  $\delta^D \mathbf{x} = 1$  for all  $D \in \mathcal{C}$

- Formally,  $E(G \times C) = \{uv; uv \in E(G), u, v \in V(G) \setminus V(C)\} \cup \{uc'; \exists v \in V(C) : uv \in E(G), u \in V(G) \setminus V(C)\}$ .

## Perfect matchings algorithm in a non-weighted graph

### Algorithm

```

1 Init:  $M := \emptyset$ 
2 while  $G$  contains an  $M$ -exposed vertex  $r$  do
3    $M' = M, G' = G$  and  $T = (\{r\}, \emptyset)$ 
4   while there exists  $uv \in E(G')$  with  $u \in B$  and  $v \notin A$  do
5     if  $v \in B$  then
6       Use  $uv$  to shrink and update  $M'$  and  $T$ 
7     else if  $v$  is  $M'$ -covered then
8       Use  $uv$  to extend  $T$ 
9     else
10      Use  $uv$  to augment  $M'$ 
11      Extend  $M'$  to a matching  $M$  of  $G$ 
12      break # Terminate the inner loop.
13 if  $r$  is still  $M$ -exposed then
14   return There is no perfect matching
15 return Perfect matching  $M$ 

```

## Minimum-Weight perfect matchings in general graphs

### Observation

Let  $M$  be a perfect matching of  $G$  and  $D$  be an odd set of vertices of  $G$ . Then there exists at least one edge  $uv \in M$  between  $D$  and  $V \setminus D$ .

### Linear programming for Minimum-Weight perfect matchings in general graphs

Minimize  $\mathbf{c}\mathbf{x}$   
 subject to  $\delta^u \mathbf{x} = 1$  for all  $u \in V$   
 $\delta^D \mathbf{x} \geq 1$  for all  $D \in \mathcal{C}$   
 $\mathbf{x} \geq \mathbf{0}$

Where  $\delta^D \in \{0, 1\}^E$  is a vector such that  $\delta_{uv}^D = 1$  if  $|uv \cap D| = 1$  and  $\delta^w = \delta^{\{w\}}$  and  $\mathcal{C}$  is the set of all odd-size subsets of  $V$ .

### Theorem

Let  $G$  be a graph and  $\mathbf{c} \in \mathbb{R}^E$ . Then  $G$  has a perfect matching if and only if the LP problem is feasible. Moreover, if  $G$  has a perfect matching, the minimum weight of a perfect matching is equal to the optimal value of the LP problem.

## Minimum-Weight perfect matchings in general graphs: Change of $\mathbf{y}$

### Updates weights and dual solution when shrinking a circuit $C$

Replace  $\mathbf{c}'_{uv}$  by  $\mathbf{c}'_{uv} - \mathbf{y}'_v$  for  $u \in C$  and  $v \notin C$  and set  $\mathbf{y}'_{c'} = 0$  for the new vertex  $c'$ . Note that the reduced cost is unchanged.

### Expand $c'$ into circuit $C$

- Set  $\mathbf{z}'_c = \mathbf{y}'_{c'}$
- Replace  $\mathbf{c}'_{uv}$  by  $\mathbf{c}'_{uv} + \mathbf{y}'_v$  for  $u \in C$  and  $v \notin C$
- Update  $M'$  and  $T$

### Change of $\mathbf{y}$ and $\mathbf{z}$ on a frustrated tree

**Input:** A graph  $G'$  with weights  $\mathbf{c}'$ , a feasible dual solution  $\mathbf{y}'$ , a matching  $M'$  of tight edges of  $G'$  and an  $M'$ -alternating tree  $T$  of tight edges of  $G'$ .

- Action:**
- $\epsilon_1 = \min \{\bar{\mathbf{c}}'_e\}$ ;  $e$  joins a vertex in  $B$  and a vertex not in  $T$
  - $\epsilon_2 = \min \{\bar{\mathbf{c}}'_e/2\}$ ;  $e$  joins two vertices of  $B$
  - $\epsilon_3 = \min \{\mathbf{y}'_v\}$ ;  $v \in A$  and  $v$  is a pseudonode of  $G$
  - $\epsilon = \min \{\epsilon_1, \epsilon_2, \epsilon_3\}$
  - Replace  $\mathbf{y}'_v$  by  $\mathbf{y}'_v + \epsilon$  for all  $v \in B$
  - Replace  $\mathbf{y}'_v$  by  $\mathbf{y}'_v - \epsilon$  for all  $v \in A$

```

1 Init:  $M' := \emptyset$ ,  $G' = G$ 
2 while  $G'$  contains an  $M'$ -exposed vertex  $r$  do
3    $T = (\{r\}, \emptyset)$ 
4   while  $r$  is  $M'$ -exposed do
5     if there exists  $uv \in E_=(G')$  with  $u \in B$  and  $v \notin A$  then
6       if  $v \in B$  then
7         Use  $uv$  to shrink and update  $M'$  and  $T$ 
8       else if  $v$  is  $M'$ -covered then
9         Use  $uv$  to extend  $T$ 
10      else
11        Use  $uv$  to augment  $M'$ 
12      else if there exists a pseudonode  $u$  in  $A$  with  $y'_u = 0$  then
13        Expand  $u$  into a circuit and update  $T$ ,  $M'$  and  $G'$ 
14      else
15        Determine  $\epsilon$  and change  $y$ 
16        if  $\epsilon = \infty$  then
17          return There is no perfect matching
18 Expand all pseudonodes and obtain  $M$  from  $M'$ 
19 return Perfect matching  $M$ 

```

## Reduction to perfect matching problem

Let  $G$  be a graph with weights  $c \in \mathbb{R}^E$ .

- Let  $G_1$  and  $G_2$  be two copies of  $G$
- Let  $P$  be a perfect matching between  $G_1$  and  $G_2$  joining copied vertices
- Let  $G^*$  be a graph of vertices  $V(G_1) \cup V(G_2)$  and edges  $E(G_1) \cup E(G_2) \cup P$
- For  $e \in E(G_1) \cup E(G_2)$  let  $c^*(e)$  be the weight of the original edge  $e$  on  $G$
- For  $e \in P$  let  $c^*(e) = 0$

## Theorem

The maximal weight of a perfect matching in  $G^*$  equals twice the maximal weight of a matching in  $G$ .

## Note

For maximal-size matching, use weights  $c = 1$ .

## Tutte's matching theorem

A graph  $G$  has a perfect matching if and only if  $oc(G \setminus A) \leq |A|$  for every  $A \subseteq V$ .
